INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with early partnership. Write: MINNESOTA MEDICINE — 289; 496 Lowry Medical Arts Building; St. Paul, 55102.

WANTED: Generalist to associate with two man partnership in Northern Minnesota. Community has a thirty seven bed hospital, X ray and laboratory technicians and nurse anesthetist. Good hunting and fishing. Adequate salary and time off. Contact: A. G. Janecky, M.D., Baudette Clinic, Baudette, Minnesota.

PROFESSIONAL AIR AMBULANCE. Multi or single engine aircraft. All weather and night flight capability, anywhere in the U. S. Oxygen, Respirator, Aspirator, Nursing service, all medications. Also full time M.D. Board Anesthesiologist providing all medical care in flight available on request. MIDWEST AIR TRANSPORTS, Operations Office, Municipal Airport, Waterloo, Iowa, Phone 319-2331083.

OFFICE SPACE now available in busy Bloomington. 713 square feet of new space in building with busy group of G.P.'s, dentist and suburban OB-GYN office. Ideal for ophthalmology, ENT or pediatrics. 8040 Penn Avenue South. 888-9211.

GENERAL PRACTITIONER WANTED by three local physicians and community. Population 3500. New 45 bed municipal hospital. Contact: Rex Beech, Sleepy Eye, Minnesota, Phone 794-5111.

WANTED GENERAL PRACTITIONER OR SURGEON space available July 15th for party interested in a very active solo professional pursuit. Ideal air conditioned suite, an opportunity that must be seen. Contact A. G. Erickson, 7033 Edgewood Avenue North, Minneapolis, or phone 533-7332.

PART TIME INTERNIST OR GENERAL PRACTITIONER. Good compensation — Midway Area. Alfred F. Anderegg, M.D.; 2500 Como Avenue, St. Paul, Minnesota.

WANTED INTERNIST, Board qualified or certified for 22-physician mixed group of general practitioners and specialists (East Range Clinic, Virginia, Minnesota). Salary first year, then full partnership. Centrally located in area of rapidly expanding economy.

WANTED: one or two general practitioners. Excellent clinic and hospital facilities. Rural practice established 18 years. Salary open, partnership if compatible. Lloyd H. Klefstad, M.D., Greenbush, Minnesota.

SACRED HEART, MINNESOTA, doctorless since 1961, wants general practitioner. Population 700, accredited hospital 10 miles away. Write: Rev. Robert Bardy, Phone 765-2547, Sacred Heart, Minnesota.

GENERAL PRACTITIONER FOR PERMANENT POSITION — salary open, under thirty-five years of age, partnership agreement negotiated in 18 months, scheduled post graduate and vacation periods. New modern medical-dental clinic with full diagnostic facilities at Highway 100 and Wayzata Blvd. Large established family practice with opportunity for surgical privileges. Contact: Alton C. Olson, M.D.; 5250 Wayzata Blvd., Minneapolis, Telephone 545-1661.

GENERAL PRACTITIONER — to join established group in progressive city of 15,000. Excellent clinic and hospital facilities. Salary open. For details contact: Richard Lehigh, Manager, Owatonna Clinic, 134 Southview, Owatonna, Minnesota 55060.

A THREE MAN group needs a fourth general practitioner in a fast-growing West St. Paul area. Begin with salary and join partnership with full participating advantages. Write: MINNESOTA MEDICINE — 326, 496 Lowry Medical Arts Building, St. Paul 55102.

FOR SALE: Family practice in community just outside of Minneapolis. Ten minutes to 100 bed hospital. Full privileges assured. Finances no problem. Write: MINNESOTA MEDICINE — 327, 496 Lowry Medical Arts Building, St. Paul 55102.

MEDICAL ART. Drawings, charts and lettering for publication, slide lectures, movies, exhibits and television. Also three dimensional models. Al Hage — 377-3198, Minneapolis.

GENERAL PRACTITIONERS — one or two wanted by two local physicians and community. Progressive community in heart of good farming section of Central Minnesota. Community owned 34-bed hospital with 45-bed nursing home wing. Excellent grade and high schools; good hunting and fishing area; golf course and other recreational facilities near by. For further information, contact Administrator Melrose Hospital, Melrose, Minnesota.

MIRACLE MILE MEDICAL CENTER: St. Louis Park has doctor's office available. This modern medical space features elevator service, air conditioning, plus plenty of parking. Call or write: Roger Wahldick at Draper and Kramer, Inc. FE 9-9441, Minneapolis.

EXCELLENT PRACTICE AVAILABLE in downtown St. Paul. Attractive six room medical office practice, furniture and equipment available. Additional available space if desirable. Call Kenneth R. Larson, M.D. 222-6555 (office) or 225-7436 (home).

CHIEF OF PSYCHIATRIC SUPERVISORY STAFF needed to help with clinical supervision and teaching in expanding (18 resident physicians) fully approved residency training program. Ideal living in active community in the heart of Michigan's Water Winter Wonderland. Newly established position requires board certification in psychiatry and additional experience in clinical supervision. Salary range depending upon qualifications, $17,393 to $21,339. Unparalleled Michigan civil service benefits. Contact Arthur F. Dundon, M.D., Clinical Director, Traverse City State Hospital, Traverse City, Michigan. An equal opportunity employer.

GENERAL PRACTITIONER WANTED: to associate with physician-surgeon in Owatonna, a Southern Minnesota community, 25,000 population. Clinic building three years old; with five large treatment rooms, lab.; x ray; central supply; two doctors' offices; pharmacy; and business offices. Located next door to 85 bed city hospital. Good opportunity for partnership. Contact: O. W. Roberts, M.D.; 920 South Cedar Street; Owatonna, Minnesota. Phone 451-4630.

PSYCHIATRIC RESIDENCIES: Positions available July 1966. Fully approved; balanced didactic and clinical experiences. Five-year career program: $8,895, $10,294, $12,048, $15,368, $16,203; NIMH General Practitioner Stipends $12,000 annually for three years. In Michigan's Water-Winter Wonderland. Contact: Dr. M. Duane Sommerness, Medical Superintendent, Traverse City State Hospital, Traverse City, Michigan. An equal opportunity employer.

GENERAL PRACTITIONER WANTED to be associated with 40-year old general practitioner. Winona, Minnesota. Excellent practice conditions. 3.5 million dollar hospital. Write: MINNESOTA MEDICINE — 322; 496 Lowry Medical Arts Building, St. Paul 55102.

LOCUM TENENS wanted for general practice in St. Paul from mid-February through March, 1966. Write: MINNESOTA MEDICINE — 328; 496 Lowry Medical Arts Building, St. Paul 55102.

WANTED: physician under 35 to assist, then share busy general practice in Long Island area of metropolitan New York with young GP. Must have or be eligible for New York license, be able to do uncomplicated OB and assist at surgery. Salary first year, then increasing percentage to full partnership. Write: Ralph E. Schlossman, M.D., 130 Lefferts Blvd., South Ozone Park, L. I., New York.

GENERAL PRACTICE Minnetonka, 20 minutes from Minneapolis loop. Ideal location for solo start with expansion to clinic. New building. Hospital nearby. Good parking. Dentist now located in one wing. Call or write: Cliff Kommedahl, 12401 Minnetonka Blvd., Minnetonka, Phone 935-8247.

A NEW, completely equipped two-doctor clinic in Southwestern Minnesota. New accredited 40-bed hospital. Large practice. Reasonable terms. Contact: Mrs. R. R. Remsburg, Tracy, Minnesota.

"...it is extremely difficult and sometimes impossible to differentiate between 'pure depression' and anxiety and it is questionable whether depression without a certain degree of anxiety really exists."

Lehmann, H. E., Canad. Psychiat. Assn. J. *4(S)*: 1-12, 1959

depression
anxiety
depression
anxiety
depression

An antidepressant designed for the clinical realities of office practice

As many physicians have reported, the large majority of neurotic depressed patients suffer from both depression and anxiety. It may be difficult to decide whether these patients are primarily depressed or primarily anxious. And yet drug treatment of only the symptom which seems more prominent may exacerbate the untreated element of the depression complex.

Consequently, it would seem that therapy specifically aimed at both the depression and associated anxiety and tension should increase success in treatment.

This is one of the important reasons why 'Deprol' has proved particularly helpful. For 'Deprol' acts rapidly both to lift the mood and to relieve the associated anxiety, tension and insomnia.

And side effects, at recommended dosage, have been infrequent and generally readily controlled.

Indications: 'Deprol' is useful in the management of depression, both acute (reactive) and chronic. It is particularly useful in the less severe depressions and where the depression is accompanied by anxiety, insomnia, agitation, or rumination. It is also useful for management of depression and associated anxiety accompanying or related to organic illnesses.

Contraindications: Benactyzine hydrochloride is contraindicated in glaucoma. Previous allergic or idiosyncratic reactions to meprobamate contraindicate subsequent use.

Precautions: *Meprobamate*—Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Side effects associated with recommended doses of 'Deprol' have been infrequent and usually easily controlled. These have included drowsiness and occasional dizziness, headache, infrequent skin rash, dryness of mouth, gastrointestinal symptoms, paresthesias, rare instances of syncope, and one case each of severe nervousness, loss of power of concentration, and withdrawal reaction (status epilepticus) after sudden discontinuation of excessive dosage.

Benactyzine hydrochloride—Benactyzine hydrochloride, particularly in high dosage, may produce dizziness, thought-blocking, a sense of depersonalization, aggravation of anxiety or disturbance of sleep patterns, and a subjective feeling of muscle relaxation, as well as anticholinergic effects such as blurred vision, dryness of mouth, or failure of visual accommodation. Other reported side effects have included gastric distress, allergic response, ataxia, and euphoria.

Meprobamate—Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Dosage: Usual starting dose, one tablet three or four times daily. May be increased gradually to six tablets daily and gradually reduced to maintenance levels upon establishment of relief. Doses above six tablets daily are not recommended even though higher doses have been used by some clinicians to control depression and in chronic psychotic patients.

Supplied: Light-pink, scored tablets, each containing meprobamate 400 mg. and benactyzine hydrochloride 1 mg.

Before prescribing, consult package circular. CD-5749

Deprol® meprobamate 400 mg. + benactyzine hydrochloride 1 mg.

WALLACE LABORATORIES / Cranbury, N.J.

too young
to be so tired...

revive interest...restore activity promptly with Alertonic®

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%; pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B_1) (10 MDR*), 10 mg.; riboflavin (vitamin B_2) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B_6), 1 mg.; niacinamide (5 MDR), 50 mg.; choline†, 100 mg.; inositol†, 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.
†The need for these substances in human nutrition has not been established.

the need for a tonic knows no age

Life *can* begin at forty—except when functional fatigue causes her to feel tired all the time; to start losing interest in friends and surroundings; to look and act older than her years. Alertonic—*a prescription tonic*—can help your patient become her normal self again. Alertonic helps relieve mild depression, revive interest and restore purposeful activity promptly...with a formula that is efficient *and* economical. Alertonic contains a mild central stimulant (pipradrol hydrochloride), 15% alcohol, essential vitamins and minerals. No hormones or MAO-inhibiting drugs are included. No iron. No iodine. One pleasant-tasting tablespoonful before each meal comprises the usual daily dose.

Indications: 1. Functional fatigue such as that often associated with: a depressing life experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Contraindications: As with other drugs with CNS-stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive-compulsive states.

Side Effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

When uncontrolled diarrhea brings a call for help

When the diarrhea sufferer has run the gamut of home remedies without success, pleasant-tasting CREMOMYCIN can answer the call for help. It can be counted on to consolidate fluid stools, soothe intestinal inflammation, inhibit enteric pathogens, and detoxify putrefactive materials—usually within a few hours.

CREMOMYCIN combines the bacteriostatic agents, succinylsulfathiazole and neomycin, with the adsorbent and protective demulcents, kaolin and pectin, for comprehensive control of diarrhea.

Indications: Diarrhea. *Contraindications:* Kaolin: Withhold if diverticulosis is present or suspected. *Precautions:* Sulfonamide: Continued use requires supplementary administration of thiamine and vita-

your ℞ for
Cremomycin
can provide relief

min K. Neomycin: Patient should be observed for new infections due to bacteria or fungi. *Side Effects:* Sulfonamide: Sensitivity reactions may occur (e.g., skin rashes, anemia, polyneuritis, fever; agranulocytosis with a fatal outcome has been reported). Reduction of thiamine output in the feces and of vitamin K synthesis has been observed. Neomycin: Nausea, loose stools possible.

Before prescribing or administering, read product circular with package or available on request.

promptly relieves diarrheal distress

Cremomycin®

ANTIDIARRHEAL

Composition: Each 30 cc. contains neomycin sulfate 300 mg. (equivalent to 210 mg. of neomycin base), succinylsulfathiazole 3.0 Gm., colloidal kaolin 3.0 Gm., pectin 0.27 Gm.

Hygroton®

brand of chlorthalidone

the long-acting diuretic

Indications
Many types of edema involving retention of salt and water.

Contraindications
Hypersensitivity, and most cases of severe renal or hepatic disease.

Precautions
Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.

Side Effects
Constipation, dizziness, dysuria, headache, hyperglycemia, hyperuricemia, leukopenia, muscle cramps, nausea, purpura, thrombocytopenia, transient myopia, urticaria, vomiting and weakness.

Average Dosage
One tablet (100 mg.) daily with breakfast.

Availability
Tablets of 100 mg. in bottles of 100 and 1000.
For full details, see the complete prescribing information.

Geigy

Geigy Pharmaceuticals
Division of
Geigy Chemical Corporation
Ardsley, New York

How does Hygroton® brand of chlorthalidone stack up against other diuretics?

Not very high. In terms of one week's therapy, that is. The usual dosage is just one tablet per day. Very often, the dosage is even lower. So a week's therapy doesn't amount to much.

That's why it's nice to work with Hygroton®, brand of chlorthalidone. You have fewer tablets to prescribe. Your patients have fewer tablets to take. And fewer to pay for.

For sheer diuretic effectiveness, choose Hygroton®, brand of chlorthalidone. It generally promotes more natruresis per tablet than the thiazides. We'll stack it up against any diuretic.

Geigy

Minnesota Medicine at a Glance

Heart Anatomy — Rinker Page 1273

Some of the anatomical features of the heart relative to normal and abnormal function are illustrated in this manuscript, and for an evaluation of the various heart disorders it is well to review this article and its illustrations.

Heart Sounds — Grissom Page 1279

Most of us think of only two heart sounds when we listen to the "lubb-dub" of the heart, but in reality there are many sounds. These sounds are made by the vibrations of the valves, the heart wall or the great vessels. If one is able to interpret each of the four heart sounds with the variations of each, one can obtain information much more meaningful than is evident from only a murmur. Some of the heart sounds are more evident in disease than they are in health and for that reason it is well to study in detail the four heart sounds as they have been so beautifully elicited by Dr. Grissom.

Ventricular Arrhythmias — Read Page 1284

Abnormal cardiac rhythms are divided into two broad categories, namely, a disturbance in the impulse conduction and a disturbance in the impulse formation. In this manuscript the arrhythmias arising as a result of an ectopic focus of impulse are principally dealt with. Calcium deficiency is known to favor an automatic impulse formation, and the cellular concentration of acetylcholine formed in the heart muscle may also have a direct bearing on the development of ectopic pacemaker in cardiac tissue. The cell membrane separates an extracellular fluid or high sodium and low potassium from an intracellular fluid of high potassium and low sodium. These ions are continuously diffusing into and out of the cell, and as they change, an electrical potential of 50 to 90 millivolts exists across the cell membrane to influence the myocardial activity. Ventricular arrhythmias are correlated with a large myocardial potassium loss. Substances which restrict the myocardial potassium loss may be effective in suppressing ventricular arrhythmia.

Cardiac Muscle — Scott Page 1292

With the electron microscope the myofibrillae, the filament, and the intercalated discs have been well illustrated. The variations in the structure from that of skeletal muscle are related to the fact that cardiac muscle fibers must contract frequently and simultaneously without long periods of recovery.

Electrolytes in Cardiac Disorders — Shaw Page 1297

The level of body fluids is regulated very closely by the balance between the fluid intake and the fluid output. The water and sodium content of the blood are under the regulatory control of vasopressin and Aldosterone. The rationale for the various types of heart failure are described.

The Chemistry of Heart Failure — Welty Page 1301

The common denominator of most forms of heart failure lies in the inability of the actomyosin system, which forms the myofibrils, to assimilate the energy of the phosphate bond and convert it into kinetic energy of contraction.

Heart failure can be divided biochemically and hemodynamically into the high output metabolic failure and low output nonmetabolic failure: the former represented by the cardiac failure of anemia, thyrotoxicosis, beri beri, etc. and the latter represented by low output congestive heart failure.

In observing the protein content of hypertrophied rat hearts it has been demonstrated that there is an increase in the myoglobulin and mitochondrial fractions. Associated with the stress factor of congestive heart failure there is an abnormal actomyosin and also an abnormality in the myosin complex.

The Myocardium and Drugs — Spencer Page 1305

The drugs used in myocardial disease can be divided essentially into three types: the myocardial stimulants which include the glycosides; the sympathomimetic amines, which also stimulate the myocardium but have a marked effect on other systems as well; and the myocardial depressant.

The cardiac glycosides are derived principally from digitalis, and though their action is principally on the heart muscle they are dependent upon calcium, potassium and other electrolytes within the body.

The sympathomimetic amines act principally upon the sympathetic nervous system. The chief disadvantage of these drugs is that the action is fleeting.

The myocardial depressant drugs act through their ability to inhibit the effects of intracellular potassium. They depress the vagus, the sinoauricular and atrioventricular nodes, and they inhibit the conduction through the bundle of His. They are indicated where depression of cardiac automaticity is desired.

Transaminase — Critz Page 1309

The determination of transaminase as an index of myocardial infarction was first described by La Due in 1954. It is suggested that the increase in the transaminase represents an attempt of the organism to convert an increased amount of amino acids into keto acids which in turn could enter the Krebs cycle and result in an elevated production of the adenosine triphosphate, thereby aiding the animal to meet the increased work load induced by the cardiac muscle. There are many conditions in which an elevated serum glutamic acid does not indicate myocardial damage; but with the clinical history of myocardial infarction, it would be rare to find a normal transaminase level.

Continued

Nutrition, Cholesterol and Heart Disease — Anderson Page 1314

A highly competitive middle-aged, slightly obese individual who is a sedentary heavy smoker with an elevated blood pressure and a serum cholesterol should have been alerted many years previous to his present condition that he would be a good bet to suffer some sort of cardiovascular accident if he did not change his living habits. Diet, along with the control of an elevated cholesterol, is only one of the many facets designed to aid in the diminution of cardiovascular disease. A philosophy of life must be developed to enable one to compete adequately with the stresses of the affluent society.

Thrombolytic Agents — Jewson Page 1363

The use of a thrombolytic agent for the purpose of lyseing a newly formed clot would appear to be a major advance in the therapy of thromboembolic cardiovascular disease. Because anticoagulants have very little benefit in restoring circulation to the ischemic area, it is postulated that the use of a thrombolytic agent might dissolve the clot and thereby provide better revascularization. The major disadvantage in the use of thrombolytic agents appears to be the formation of antibodies. Retreatment would then be especially difficult because of the increased amount of streptokynase that would have to be used to neutralize the antibodies and the hypersensitivity that might therewith develop.

Nonmetallic Implants — Nelson and Ivins Page 1371

This is a review of the various types of grafts, implants, and tissue substitutes which have been used primarily in the field of orthopedic surgery. The various criteria for the use of nonautogenous material are detailed, the principal obstacles to the use of exogenous material being antigenicity and rejection, foreign body reaction, loss of function, infection, and inadequate knowledge of the final fate of implants.

The processed heterologous bone graft, based on the work of Anderson et al., appears to offer a considerable number of advantages and can be commercially prepared.

The tissue substitutes, polyurethane, acrylic, tetrafluoroethylene, and the silicones offer interesting possibilities for the future.

Coronary Blood Flow — Geber Page 1387

For a provocative evaluation of the regulatory factors of coronary blood flow, this manuscript should be studied. The author points out that the evidence suggesting that the coronary smooth muscle cells react differently than the rest of the vascular beds of the body is inconclusive, if not altogether incorrect.

Physician's Diary

Let friendship creep gently to a height; if it rushes to it, it may soon run itself out of breath. — Fuller

Dr. N. N. Sonnesyn of LeSueur became chief of the medical staff at the Minnesota Valley Memorial Hospital at the hospital's staff meeting in June. **Dr. Dale Bergeron** former chief has accepted an appointment at the Marine Hospital in San Francisco, California.

the difference between cough and relief

Benylin® Expectorant

Each fluidounce contains: 80 mg. Benadryl® (diphenhydramine hydrochloride, Parke-Davis); 12 grains ammonium chloride; 5 grains sodium citrate; 2 grains chloroform; 1/10 grain menthol; and 5 per cent alcohol.

for relief of coughs due to colds or allergy

PRECAUTIONS: Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this preparation. Hypnotics, sedatives, or tranquilizers, if used with BENYLIN EXPECTORANT, should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENYLIN EXPECTORANT. PACKAGING: Bottles of 4 oz., 16 oz., and 1 gallon.

PARKE-DAVIS

PARKE, DAVIS & COMPANY, Detroit, Michigan 48232

Brewer Diagnostic Kits

Complete Serological Screening Tests For Syphilis . . .

The RPR Card Tests make use of a specially prepared, carbon-containing RPR Card antigen. The particle size and other characteristics of the carbon is such that when a reactive specimen is encountered, flocculation occurs, and there is a coagglutination which is readily visible to the naked eye. Individual tests, including the collection of blood and separation of plasma can be performed in 7 to 8 minutes.

Confirming earlier findings with the RPR Card Test[1-10] Reed[11] in reporting on 63,800 specimens had an overall agreement of 98.5% in a recent comparative study with other routine screening procedures.

The RPR Card Tests, with their low cost, ease of performance, high sensitivity and specificity, are without peer in situations that demand rapid testing of patients, enabling the physician to initiate prompt treatment of early infectious syphilis.

Specify the RPR Card Test as the screening procedure on serum or plasma samples submitted to your State Approved Laboratory.

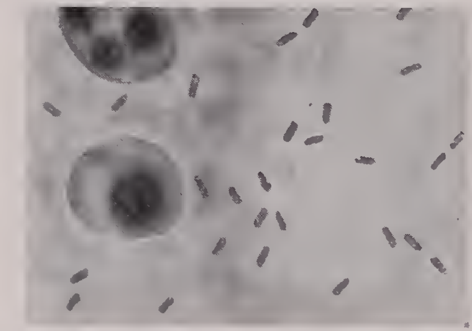
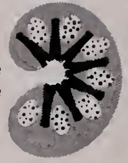
to clear an infected stream





treat the source
with optimal dosage

NegGram®

Brand of
nalidixic acid

Treat the source. The gram-negative pathogens that cause most urinary tract infections. Treat them with a specific drug. NegGram. Clinical tests show that in adults two 500 mg. NegGram Caplets® orally four times a day will clear up most gram-negative urinary infections. Quickly...effectively...with minimal side effects.

Gram-negative urinary infection—cystitis, pyelitis, pyelonephritis, prostatitis, urethritis? Start first with NegGram..."a good 'starting' drug."[1] NegGram "...treatment may be first choice in potentially curable gram negative bacterial urinary infections."[2]

Indications: Urinary tract infections caused by gram-negative and some gram-positive organisms.

Side effects: Mainly mild, transient gastrointestinal disturbances; in occasional instances, drowsiness, fatigue, pruritus, rash, urticaria, mild eosinophilia, reversible subjective visual disturbances (overbrightness of lights, change in visual color perception, difficulty in focusing, decrease in visual acuity and double vision), and reversible photosensitivity reactions. Marked overdosage, coupled with certain predisposing factors, has produced brief convulsions in a few patients.

Precautions: As with all new drugs, blood and liver function tests are advisable during prolonged treatment. **Pending further experience, like most chemotherapeutic agents, this drug should not be given in the first trimester of pregnancy. It must be used cautiously in patients with liver disease or severe impairment of kidney function.** Because photosensitivity reactions have occurred in a small number of cases, patients should be cautioned to avoid unnecessary exposure to direct sunlight while receiving NegGram, and if a reaction occurs, therapy should be discontinued. The dosage recommended for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Bacterial resistance may develop.

When testing the urine for glucose in patients receiving NegGram, Clinistix® Reagent Strips or Tes-Tape® should be used since other reagents give a false-positive reaction.

Dosage: Adults: Four Gm. daily by mouth (2 Caplets® of 500 mg. four times daily) for one to two weeks. Thereafter, if prolonged treatment is indicated, the dosage may be reduced to two Gm. daily. Children may be given approximately *25 mg. per pound* of body weight per day, administered in divided doses. The dosage recommended above for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Until further experience is gained, infants under 1 month should not be treated with the drug.

How supplied: Buff-colored, scored Caplets® of **500 mg. for adults,** conveniently available in bottles of 56 (sufficient for one full week of therapy) and in bottles of 1,000. **250 mg. for children,** available in bottles of 56 and 1,000.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

President's Letter

In a few months Public Law No. 89-97 (Medicare) will be a fact of life which most of us did not ask for or think necessary. Whether we like it or not we cannot ignore it. Numerous conferences between administrative personnel of the Department of Health, Education, and Welfare and the medical profession have made it evident that government administrators are disposed to initiate Medicare with as little disturbance of the existing doctor-patient relationship as possible. Provisions are in the law which should result in the approval of almost all of the Minnesota hospitals which are presently licensed by the State Board of Health and there is nothing in the law which will prevent free choice of physician by the patient. The freedom of the physician to make his usual and customary charges and to look to the patient for payment to him is maintained, since the contract under Part B of Medicare is between the patient and the selected carrier unless the doctor elects to take an assignment of fees from the patient. Health, Education, and Welfare officials are emphatic that "reasonable fee" referred to in the law is to be interpreted as the usual and customary fee without regard to the patient's financial status. This will apply to those who at present may be charity patients and under a welfare fee schedule which is definitely below the usual and customary.

Utilization committees will be required in all participating hospitals and nursing homes. This concept is not new; in fact, many hospital staffs throughout the country are cooperating with such committees which have been formed voluntarily with the full approval of medical societies. The new law is broadly worded requiring only that there must be physician representation on Utilization Committees. Health, Education, and Welfare officials have also stated that they will endeavor to make certification for hospitalization and home care as simple as possible.

Most of the regulations incident to the new law as presently interpreted are not different in principle from those which the medical profession has accepted. The proportion of the population covered is, of course, more extensive than any heretofore encountered.

Those engaged in negotiation with governmental agencies about the details of this or any other law are traditionally suspicious that interpretation made at the inception will be more acceptable than that which may subsequently be deemed necessary. In my opinion it will be in the best interests of the practicing profession to cooperate fully with the present administration of Health, Education, and Welfare and the appointed carriers in order that we may have the maximum representation to maintain and strengthen the traditional freedoms of the physician in the application of Medicare. To do otherwise will give an advantage to those who do not fully represent the medical profession. Our opinions are being honestly solicited, and they should be thoughtfully given and diligently defended.

It is significantly appropriate that in this issue of MINNESOTA MEDICINE special recognition is being given to Ancker Hospital. The alumni of its training programs are numerous in this and the surrounding states. In offering our congratulations and best wishes to all those associated with Ancker Hospital, we know that the future is very bright.

JMStickney M.D.

J. M. Stickney, M.D.
President

a significant price decline in the cost of V-Cillin K®
150 cc. (When Mixed) M-126
V-CILLIN K®
POTASSIUM PHENOXYMETHYL PENICILLIN
PEDIATRIC
125 mg.
(200,000 Units) per 5 cc
100 TABLETS No. 1831
V-CILLIN K®
POTASSIUM PHENOXYMETHYL PENICILLIN TABLETS, U.S.P.
250 mg. (400,000 Units)
CAUTION—Federal (U.S.A.) law prohibits dispensing without prescription.
Lilly
Eli Lilly and Co. Indianapolis, U.S.A.

V-Cillin K now costs approximately 21 percent less. This significant price decline constitutes a substantial saving and still offers these important benefits over penicillin G:

The effectiveness of intramuscular penicillin. Just three 250-mg. doses daily provide total twenty-four-hour penicillin blood levels equal to those achieved by injection of 600,000 units of procaine penicillin G. A fourth dose increases daily penicillemia to levels 35 percent above those achieved by injection.

Consistent dependability—even in the presence of food. Comparative pharmacologic data show that V-Cillin K produces peak blood levels *twice* as high as those of penicillin G, with *half* the dose.

New, thin coating . . . new size and shape. The new coating eliminates the characteristically bitter taste of oral penicillin and makes V-Cillin K tablets easy to swallow. The new shape makes them easy for physicians and pharmacists to identify.

Indications: V-Cillin K is an antibiotic useful in the treatment of streptococcus, pneumococcus, and gonococcus infections and infections caused by sensitive strains of staphylococci.

Contraindications and Precautions: Although sensitivity reactions are much less common after oral than after parenteral administration, V-Cillin K should not be administered to patients with a history of allergy to penicillin. As with any antibiotic, observation for overgrowth of nonsusceptible organisms during treatment is important.

Usual Dosage Range: 125 mg. (200,000 units) three times a day to 250 mg. every four hours.

Supplied: Tablets V-Cillin K, 125 or 250 mg., and V-Cillin K, Pediatric, 125 mg. per 5-cc. teaspoonful, in 40, 80, and 150-cc.-size packages.

V-Cillin K®

Potassium Phenoxymethyl Penicillin

Additional information available to physicians upon request. Eli Lilly and Company, Indianapolis, Indiana.

Use of Digitalis in Pediatric Patients

Essentials for the Practicing Physician

ROSWITH I. LADE, M.D.*
St. Paul, Minnesota

IN THE PEDIATRIC age group, almost 90% of the patients who develop congestive heart failure are less than one year old.[1] The majority of these die in infancy.[2] In the first days and weeks of life, unsuspected severe congenital heart disease may suddenly manifest itself with respiratory distress and rapid progression of circulatory failure to death. An appreciable number of these infants have congenital heart lesions which are potentially correctable or can be alleviated by prompt surgery. Examples are coarctation of the aorta, aortic atresia and pulmonary atresia. The opportunity for successful treatment, however, rapidly adminishes with time, once cardiac distress has become apparent. Survival will be improved if special diagnostic procedures and emergency surgery can be carried out prior to exhaustion of the small energy reserves, depletion of catecholamines** and development of severe metabolic acidosis resulting from tissue hypoxia. The indication for emergency surgery is given in many instances (coarctation of the aorta, for example) if the response to digitalis treatment is unsatisfactory. Several critical, life-saving hours may, therefore, be gained if the first physician to examine the infant in distress, whether he be the obstetrician, general practitioner, pediatrician, resident, or intern on call, can initiate digitalization and other supportive therapy. Postponement of treatment is then avoided while arrangements are made for emergency transfer to a hospital with a Pediatric Cardiology Service.

The following data and discussion are designed to serve the practicing physician in his diagnostic and therapeutic considerations so that the delay encountered by the consultation of special literature will be minimal.

Diagnosis of Congestive Heart Failure

Congestive heart failure in infants is usually associated with an increased respiration rate (a rate above 55 per minute in the newborn at rest if counted over an entire minute) and with inspiratory retraction of the lower ribs anteriorly. Inspirations may become less labored due to exhaustion of the infant as heart failure progresses, while the respiration rate tends to remain in the range of 70 to 100 per minute or may increase further with ineffective ventilation. Rales are rarely found in infants except in the terminal phase of pulmonary edema.

---

*From the Department of Pediatrics, Pediatric Cardiology Service, Ancker Hospital, St. Paul, Minnesota, and Department of Pediatrics, University of Minnesota Hospitals, Minneapolis, Minnesota.

**See Test Your Word Score Page 1491.

The blood pressure tends to be low in circulatory failure. Excessive fatigue with feeding, vomiting, and failure to thrive may be the first signs of heart failure in infants if the onset is more gradual.

The Heart Sounds

A heart murmur may be absent or masked by respiratory noises in the presence of marked tachypnea. The heart sounds may or may not appear muffled; a diastolic gallop rhythm is almost diagnostic of myocardial failure. The heart rate is usually fast during rest (above 160 per minute in young infants with failure), but the normal range is wide. Definitely abnormal fast heart rates, above 200 and occasionally exceeding 300 per minute, may occur with paroxysmal supraventricular tachycardia in infants and result in heart failure. This condition should be suspected if the rate is regular and too fast to be counted by auscultation. The diagnosis of PAT is established electrocardiographically.

Cyanosis

Cyanosis may not be noticable initially but may develop as a result of (a) low cardiac output with circulatory stasis manifested by slow disappearance of a blanched ring from pressure of the stethoscope, (b) incomplete oxygenation of pulmonary venous blood in pulmonary congestion and edema (usually improving somewhat with oxygen treatment), or (c) in newborns a significant right to left shunt through the patent or reopened ductus arteriosus and the foramen ovale secondary to increased pulmonary vascular resistance in hypoxia and hypercarbia. Severe cyanosis may be present without heart failure in intracardiac defects producing a shunt of venous blood into the arterial circulation, as in tetralogy of Fallot, or it may be associated with a failing heart in emergency conditions of the newborn as in atresia of the pulmonary valve with normal aortic root.

Enlarged Liver

The most sensitive index of cardiac failure in the infant is enlargement of the liver,[3] i.e., if the liver in newborns is palpable more than 3 cm. below the right costal margin when measured in the medioclavicular line, has lost its sharp edge, and is tender particularly when engorgement is acute. Emphysema of the lung with low position of the diaphragm may result in an erroneous impression of liver enlargement. Chest x-rays are helpful in recognizing this condition.

Peripheral edema is often manifested by a "puffy face" and a lustrous or shining appearance of the skin. Pitting edema is rare in infants. Systemic venous engorgement is a valuable sign in older children.

Heart Size

The heart size is clinically often difficult to evaluate in infants. X-ray evidence of heart enlargement is generally present in cardiac failure. Exceptions include congenital stenosis of the pulmonary veins, cor triatriatum, atresia of the common pulmonary vein with total anomalous pulmonary venous connection and other obstructive lesions at or above the mitral valve, all of which lead to engorgement of the pulmonary veins and may be responsible for circulatory failure in infancy. A reticular or granular appearance of the lung fields associated with normal heart size is a characteristic finding in this entity. If x-ray films are less than ideal, pulmonary congestion and edema are sometimes difficult to differentiate from pneumonia or increased vascularity due to an intracardiac left to right shunt. Since pneumonia and heart failure may concur, in clinically doubtful cases a therapeutic trial of digitalization in connection with antibiotic treatment is justified. The heart size in newborns may not be significantly increased at the onset of cardiac distress, but marked dilatation may develop within a few hours. Portable films taken at less than five to six feet or the presence of a large thymus gland can lead to overdiagnosis of cardiac enlargement, while the cardiac size may be underestimated in the presence of pulmonary emphysema, usually present in cyanotic congenital heart disease.

Therapy of Heart Failure

Supportive medical therapy[4]

Positioning in a semi-upright infant seat in a tent or isolette with humidified oxygen for relief of dyspnea and cyanosis.

Morphine in a dosage of 0.1 mg. (to 0.2 mg.) per kg. body weight in very restless infants with pulmonary edema[4] to prevent exhaustion due to excessive restlessness.

Mercurial diuretics: (a) meralluride sodium injection (mercuhydrin sodium) available in ampules and vials: each ml. contains 39 mg. mercury and 48 mg. theophylline; or (b) mercaptomerin sodium (thiomerin sodium) available in vials, solution and dry form (1.4 and 4.2 gm.): each ml. contains 40 mg. mercury. The dosage of either drug for infants in the first few months is 0.1 ml. I.M.; for older infants 0.20 to 0.25 ml., and beyond infancy up to 0.5 ml. I.M. This dosage should be given only once daily and not for more than two or three days. Increased loss of potassium in the urine must be expected; therefore great caution is required to prevent digitalis intoxication due to hypokalemia. Diuretics are useful in emergency treatment of pulmonary edema. If the onset of cardiac failure is more gradual, it is preferable to defer mercurials to reduce the risk of digitoxicity during digitalization.

Restriction of sodium intake in the infant by using Lonalac formula (Mead Johnson). The prepared formula contains 1.1 mEq. of sodium per liter. After the initial beneficial sodium depleting effect, this formula may produce a low sodium syndrome if continued over long periods. If edema is relieved, it should be replaced by Similac 60/40 or SMA 26 (Ross Laboratories or Wyeth Laboratories respectively). Both of these formulas contain sodium in physiological amounts (6.5-7 mEq/L.) corresponding to breast milk. They are, therefore, safer than other formulas with higher sodium contents (Similac 11.2 mEq/L., evaporated milk in 1:1 dilution 16.9 mEq/L., whole cow's milk 16.9 mEq/L.). Frequent oral suctioning — if secretions are present — is indicated to prevent additional respiratory embarrassment. Gavage feeding in severe distress will preserve the infant's energy.

Digitalis

Digitalis is the most important drug in the treatment of failure in infants. It is recommended, although not equally effective, in all forms of heart failure. Probably the only contraindication is digitoxicity.[4]

TABLE I
Dosage of Digoxin (Lanoxin) for Infants and Children

		Total Digitalizing Dose*		
Age	Method of Administration	mg./kg.	per M^2 Body Surface Area	Total Daily Maintenance Dose**
Newborn (under 2 wk.) and premature infants	Intravenous or Intramuscular	0.03-0.05	0.6-0.75 mg.	1/10-1/5 of total digitalizing dose
Infants under 2 yr. (after newborn period)	Oral	0.06-0.08	1.5 mg.	1/5-1/3 of total digitalizing dose
	Intravenous or Intramuscular	0.04-0.06		1/10-1/5 of total digitalizing dose
Children over 2 yrs.	Oral	0.04-0.06	1.5 mg.	1/5-1/3 of total digitalizing dose
	Intravenous or Intramuscular	0.02-0.04		1/5 of total digitalizing dose

*Recommended method of administration with consideration of individual variation: 1/2 total dose at once followed by 1/4 total dose in 6-8 hours, and 1/4 total dose in another 6-8 hours, with maintenance therapy instituted 12 hours thereafter.

**Divided in 2 equal parts and given at 12-hour intervals.

CAUTION: Patient should not have had digitalis or derivatives for 2 weeks or more.

Digitalization is considered a therapeutic bedside experiment. The smallest effective dose is the safest and must be determined by close clinical observation and judgment of the effect. Tables serve to calculate the range within which most likely effective digitalization is possible (Table 1, Reference 5). Toxic effects may occur within this range if hepatic or renal function is decreased, and if electrolyte abnormalities, especially low potassium blood levels, are present or develop during treatment with diuretics or parenteral fluid therapy. Calcium given intravenously enhances digitalis effect and may precipitate toxicity.

'Lanoxin' brand digoxin is the preferred drug in pediatrics for a number of reasons. It is commercially available for parenteral and oral administration in concentrations suitable for infant dosages without further dilution (Table 2). The maximal effect is obtained rapidly: on intravenous administration in two to three hours, on oral or intramuscular administration in three to four hours. The excretion is so rapid that slightly toxic effects disappear usually within one day, and maximal duration of toxicity is unlikely to exceed two days. Most of the drug is excreted within 48 to 72 hours.[4] In order to maintain stable digitalization, however, the maintenance dose must be given in at least two divided parts at intervals of 12 hours.

TABLE 2
Recommended Technique of Digitalis Administration in Pediatric Patients

A. Lanoxin brand Digoxin Injection (Burroughs Wellcome) for intramuscular or intravenous use is available in 2 cc. ampules each containing 0.5 mg. (0.25 mg. per cc.)
CAUTION: Do not confuse with Digitoxin!
A standard glass tuberculin syringe with divisions of 0.01 cc. should be used if dosages for infants are to be measured. Disposable plastic syringes are less accurate and not recommended for this purpose.
The needle used for the injection should be filled with Lanoxin when the amount is measured so that the exact dose is delivered by injection.
The cc. scale of the syringe should always be used for measurement. Estimations on the minim scale are inaccurate and have resulted in errors and overdosage.
Before injection the nurse should check with the physician to exclude errors in measurement of the calculated amount.
The following conversion table may be helpful for the measurement of infant dosages:

1.0 cc. = 0.25 mg. Lanoxin Injection
0.5 cc. = 0.125 mg. Lanoxin Injection
0.4 cc. = 0.1 mg. Lanoxin Injection
0.2 cc. = 0.05 mg. Lanoxin Injection
0.1 cc. = 0.025 mg. Lanoxin Injection
0.05 cc. = 0.0125 mg. Lanoxin Injection
0.04 cc. = 0.01 mg. Lanoxin Injection
0.03 cc. = 0.0075 mg. Lanoxin Injection
0.02 cc. = 0.005 mg. Lanoxin Injection
0.01 cc. = 0.0025 mg. Lanoxin Injection

B. "Lanoxin" brand Digoxin Elixir Pediatric (Burroughs Wellcome) for oral use is available in bottles of 2 fl. oz. equipped with calibrated dropper. Each cc. of oral Lanoxin contains 0.05 mg. Note the difference in concentration between the oral and parenteral preparation! See Table 1 in regard to the differences in oral and parenteral dosages.

Administration of Digitalis

The intramuscular route, and, in emergencies, the intravenous route is used to initiate digitalis therapy in infants and small children to avoid uncertainty of absorption associated with vomiting and spitting up.

The range of the total digitalizing dose should be calculated on the progress sheet of the chart according to the digitalization schedule (Table 1). In order to prevent fatal errors in decimal points, the dose should be recalculated independently by another physician or a nurse. For technical details see Table 2.

Example

A two-day-old newborn of 3000 gm. body weight would require a total dose of Lanoxin for parenteral digitalization between 0.09 mg. and 0.15 mg., which corresponds to 0.36 cc. and 0.6 cc. (Table 2). A dose near the lower range is then tentatively selected so that it can be divided and measured accurately, for example, 0.10 mg. Lanoxin = 0.4 cc. The initial dose equal to ½ of total is 0.05 mg. contained in 0.2 cc. and is given at once intramuscularly or intravenously. The second dose equal to ¼ of total is 0.025 mg. in 0.1 cc. and is given four to eight (usually six) hours after the first dose intramuscularly. The third dose equal to ¼ of total is 0.025 mg. in 0.1 cc. and is given four to eight (usually six) hours following the second dose intramuscularly.

The apical pulse is checked at hourly intervals by an experienced nurse for any evidence of irregularity, bradycardia or tachycardia. Abnormal findings are immediately reported to the physician. An electrocardiogram is taken whenever any arrhythmia is suspected and routinely between the second and third dose. The infant is re-evaluated by the physician for any signs of toxicity before the second and third doses are given. If the desired effect has not been obtained four to eight hours after the previously calculated total dose has been given and no signs of toxicity are present, another quarter of the digitalization dose may then be given. This would increase the total dose required for digitalization to 0.125 mg., which is still below the upper range calculated initially for this infant. If this dose is effective, and no toxic signs are present, intramuscular maintenance therapy is begun 12 hours later.

The total daily maintenance dose for this infant is calculated on the basis of the actual digitalization dose of 0.125 mg. according to Table 1. The range is 0.0125 mg. (=0.05 cc.) to 0.025 mg. (=0.1 cc.). An average dose would be 0.01875 mg. (=0.075 cc.). Since volumes of less than 0.01 cc. cannot be measured with a tuberculin syringe, the dosage must be adjusted to a practical figure, for example, 0.02 mg. (=0.08 cc.). The total maintenance dose is then divided into two equal parts of 0.01 mg. (=0.04 cc.) of Lanoxin and injected intramuscularly every 12 hours to maintain stable digitalization. Further adjustments must be made according to the individual needs and as weight and age increase. In infants beyond the newborn period who do not spit up, and in older children, maintenance therapy is usually carried out with oral Lanoxin. Note the difference in oral dosage (Table 1) and in concentration of Lanoxin in the elixir for oral use (Table 2).

A favorable response to digitalization is associated with relief of dyspnea, improvement of tachypnea and tachycardia, recession of hepatomegaly, relief of edema, improvement of color and of food intake.

Digitalis Toxicity

While the electrocardiogram is not helpful to determine therapeutic efficacy of digitalis, it is an important aid in the recognition of toxicity. Almost any arrhythmia can be produced, including atrioventricular dissociation, atrial and ventricular premature beats, intra-atrial atrioventricular and bundle branch block, nodal tachycardia, atrial flutter and fibrillation, and ventricular tachycardia and fibrillation.

The infant may show an unusual lethargy, vomiting, diarrhea, abdominal pain and lack of appetite. Mild degrees of intoxication may develop as the result of slow accumulation during maintenance therapy and usually are easily treated by withdrawal of the drug and oral administration of potassium in the form of orange juice. After elimination of all signs of toxicity maintenance with a lower dose is resumed. Severe intoxication is almost always due to errors in dosage, confusion of glycosides with similar names, or accidental poisoning with tablets kept unlocked at home.

Treatment

Prevention of digitalis intoxication requires great care. The treatment of a serious toxic arrhythmia keeps one or more physicians at the bedside for many hours. In such instances, the following are recommended:[6]

A written order to stop the digitalis.

If kidney function is adequate, the electrocardiogram shows no evidence of hyperkalemia and no vomiting is present, oral potassium therapy with potassium triplex (15 mEq. of potassium per teaspoon), 1 teaspoonful three times daily or potassium gluconate (Kaon elixir) (20 mEq. of potassium per tablespoonful,) 2 tablespoonfuls daily.

If oral medication is impossible or ineffective, intravenous potassium administration may be considered. Continuous electrocardiographic monitoring and bedside interpretation by an experienced electrocardiographer are necessary. The solution should contain no more than 40 mEq. of potassium chloride in 500 cc. of dextrose (5% in water) and the total dose should not exceed 2 mEq. per kg. body weight (1 mEq. per pound). Administration must be very cautious to avoid potassium intoxication. The maximum dose for a 3-kg. infant would be 6 mEq. which equals 75 cc. of above solution. The infusion is started in a slow intravenous drip and is stopped if the arrhythmia disappears or peaking of the T wave occurs.

Potassium is not indicated in complete heart block since it may depress the atrioventricular node and ventricular conduction and may cause asystole. Instead isoproterenol (Isuprel) may be tried in 0.1 mg. doses intravenously.

Depression of the ionization of calcium may effectively reduce digitoxicity, since a synergistic action exists between calcium ion and digitalis.

Ethylenediamine tetra-acetic acid has been found hazardous because of severe hypotension, damage of proximal renal tubular cells, and other side effects.[7] It has recently been suggested to use sodium citrate in 4% solution or acid-citrate-dextrose solution (Baxter) intravenously as a chelating agent.[7] Our experience with this treatment is limited to one infant in which no untoward reactions occurred. The solution was given cautiously intravenously over four to five hours as indicated by the electrocardiographic findings. An anesthesiologist was in attendance to maintain a clear airway and respiration if this should become necessary. One should be aware of the hazard of tetany during this treatment.

Adequate treatment of the infant with cardiac problems is a challenge to everybody concerned with his care.

WHAT'S YOUR DIAGNOSIS?

A white female, aged 46, gave a history resembling biliary colic. A cholecystogram revealed a nonfunctioning gallbladder, but there was a ring-like area of calcification 12 millimeters in diameter having the characteristics of a partially calcified gallstone (Figure 1). She was operated upon in January 1952, when the gallbladder was found to be thickened but no stone identified. The gallbladder was then removed. Postoperative convalescence was satisfactory.

She was then well until January 1954 when she developed nausea and right upper quadrant pain and, on occasions, had episodes of fever, bloating, intolerance to cabbage, apples, and a few other foods. These intermittent symptoms persisted, and in August 1957 an intravenous cholangiogram revealed "gallbladder filled with opaque material and multiple noncalcified stones." At this time she was again operated. The common duct was explored and also the liver up to the bifurcation of the right and left hepatic ducts, on the basis that there might be a intrahepatic second gallbladder. None was found. She had satisfactory healing but persisted in having intermittent bouts of fever and pain in the right hypochondrium. Six months after the second operation she was explored again. What is your diagnosis? Turn to page 1457.

Fireplace

What is more cheerful, now, in the fall of the year, than an open woodfire? Do you hear those little chirps and twitters coming out of that piece of applewood? Those are the ghosts of the robins and bluebirds that sang upon the bough when it was in blossom last spring. In summer whole flocks of them come fluttering about the fruit trees under the window; so I have singing birds all the year round. — Thomas Bailey Aldrich

Gardner's Syndrome

BOYD SHOOK, M.D.*
HAROLD WINDSCHITL, M.D.*
St. Paul, Minnesota

FAMILIAL POLYPOSIS of the colon, associated with hard and soft superficial tumors such as exostoses, osteomas, fibromas, and desmoid** tumors, has come to be known as Gardner's syndrome.[1] It is inherited as an autosomal dominant characteristic. Because of the high incidence of carcinoma,[2] early recognition and therapy is important, as one half of these patients have carcinoma by the time they are 30 years old. We have recently encountered a young woman at Ancker Hospital who serves as a reminder that we should be alert to lesions which predispose to carcinoma.

Case Report

The patient is a 29-year-old white female who first noted a nodular growth in her abdomen during her first pregnancy at age 22. This was excised and found histologically to be a desmoid tumor (Figure 1). During the next six years she had numerous recurrences and excisions, one such recurrent growth causing obstruction of her right ileofemoral artery. A teflon prosthesis was used to restore circulation to her right leg. In an attempt to excise the tumors completely the anterior abdominal wall was replaced with teflon mesh. As this was unsuccessful, a course of radiotherapy was given, using Cobalt 60, with the left upper quadrant receiving 5150 rads over a 48-day period. As the tumors appeared to be shrinking, the right lower quadrant was then treated to a total dose of 5030 rads over a 66-day period.

The patient then did well for 11 months, at which time she noted rectal bleeding both around the stool and mixed with it. She was assured that this was not unusual, and no diagnostic or therapeutic steps were undertaken. Three months later, she con-

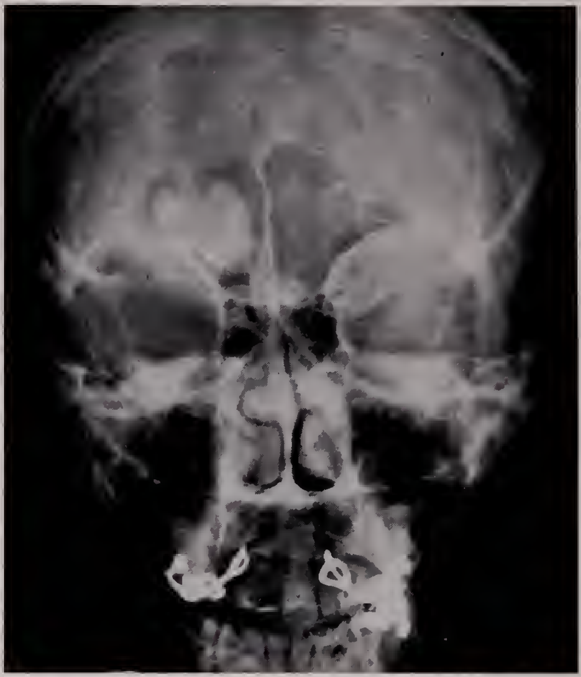

Fig. 4 — Radiograph of skull demonstrating large osteoma in frontal sinus. Also note extensive dental prosthetic devices.

sulted a proctologist who felt and visualized a large mass in her rectum. An exploratory laporatomy was done immediately, at which time carcinoma was found in multiple lymph nodes, the omentum, and both lobes of the liver (Figure 2). A transverse colostomy was performed to avoid obstruction of the colon. Multiple polyposis was observed in the colon.

She was informed of the metastatic nature of her disease and of the prognosis. Because of severe and almost constant pain, she elected to try a course of chemotherapy.

Physical examination at the time of admission revealed a frightened and cachectic young woman. Positive findings included exostoses over the skull, a hard nodular liver, and a rigid, indurated abdominal wall. There was a hard mass in the rectum, easily palpated, which was felt to be about 10 cm. in diameter. Vaginal examination demonstrated a "frozen pelvis" with this large mass almost obstructing the introitus.

Laboratory data included a normal urinalysis. Hematocrit was 30%. White blood count was 6,200 per cu. mm. with a normal differential. Blood urea nitrogen was 10 mgm%. Serum glutamic oxalacetic transaminase was 27 units. Alkaline phosphatase was 10.8 units. A barium enema demonstrated several polyps (Figure 3) in the distal colon. Radiographs of the chest were normal. Radiographic examination of the skull demonstrated a large osteoma in the frontal sinus (Figure 4).

Chemotherapy

The patient was started on intravenous 5-Fluorouracil, using the regimen of Ansfield,[3] with immediate reduction of pain and increase in well-being. The mass in her rectum has now shrunk approximately 60%. At the present time she has gained 12 pounds and requires almost no medication for pain. She has tolerated the medication well.

A Safe Gastrostomy Tube for Infants

H. D. ROOT, M.D., Ph.D., F.A.C.S.*
St. Paul, Minnesota

THE EMPLOYMENT of gastrostomy tubes in infants is often necessary in a variety of conditions such as congenital esophageal atresia, esophageal perforation, corrosive stricture or neurogenic dysphagia. Although used as a temporary measure the type of tube chosen for the gastrostomy is critical. Whereas a Foley or Malecott catheter #18 or #20 French may be satisfactory and relatively safe in the normal adult stomach, the newborn infant presents a different problem, especially a premature infant with esophageal atresia, into whose stomach no fluid or food has ever entered. In this latter group the wall of the microstomach is very friable and soft and cannot long withstand continued pressure by any device without resultant full thickness necrosis and perforation. Any tube with a tip which could impinge on the gastric wall is thus potentially lethal. A #10 F or #12 F mushroom tip catheter, although safer to use than a Foley or Malecott catheter, has the disadvantage of a narrow lumen in proportion to outside diameter, predisposing to plugging by food. Thus it may be necessary to use a larger tube to gain lumen size; but a large gastrostomy in these infants carries the high risk of a gastrocutaneous fistula. Moreover, granted success when the gastrostomy tube is placed, the rigid tips of the tubes tend to dilate the gastrostomy tract when changed, again fostering a gastric fistula.

Mindful of and sadly experienced in the above complications, we have utilized without ill effects and without complication in both infants and adults, a soft, rubber Davol T-tube, size #12 F to #16 F, such as is routinely used for common bile duct drainage. These tubes are relatively thin-walled and soft, yielding a maximum inside diameter for over-all size, yet rigid enough to withstand the negative pressure of gastric suction and tissue pressure of the abdominal wall.

These tubes are prepared with short (1.5

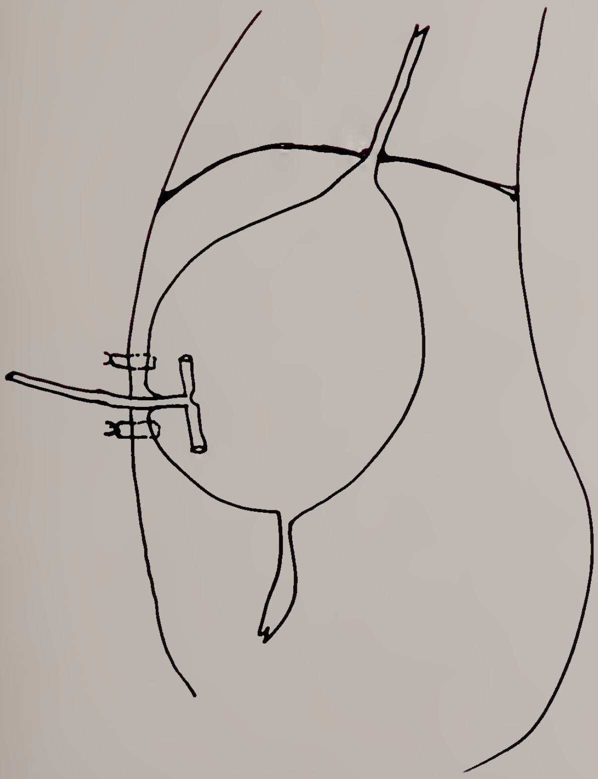

Fig. 1 — This is an outline drawing showing placement of the gastrostomy T-tube by the Stamm technique, emphasizing the subsequent suture fixation of the stomach to the anterior abdominal wall.

cm.) transverse limbs, the tips of which are beveled away from the vertical limb, with a plug cut out of the transverse limb opposite the point of insertion of the vertical limb (Figure 1). The short limbs thus prepared are advantageous in several respects: 1) they facilitate ease of infusion of gastrostomy feedings with little likelihood of obstruction by coagulated feeding; 2) they are firm enough to resist moderate traction yet atraumatic when removed, thereby preventing dilation of the tract and predisposition to gastric juice leakage; and 3) there is no sharp rigid portion or tip of the tube to press on the gastric wall at any point, thus preventing gastric necrosis and perforation.

The T-tube is inserted into the stomach either with a Stamm technique, i.e., multiple concentric serosal purse-string sutures forming a serosa-lined tract perpendicular to the surface of the stomach, or with the Witzel technique, whichever is preferred. We have found however, that a Stamm gastrostomy utilizing the above described T-tube can be easily performed in the newborn through a small upper abdominal incision under local anesthesia. Upon insertion the limbs of the tube are pulled gently against the anterior gastric wall without fear of pressure necrosis of either the anterior or the posterior gastric wall. The vertical limb of the tube is finally secured by a catgut suture in the gastric wall and is passed through a stab wound in the abdominal wall lateral to the incision; then the stomach is sutured to the abdominal wall at the point of exit.

In addition, we are careful to utilize monofilament stainless steel wire to fix the T-tube to its point of exit from the skin. Moreover, we instill in the tube twice daily 5 cc. of a solution of 100,000 units of varidase at the completion of a feeding, thereby preventing coagulation of the formula upon the inner lining of the tube.

IT'S THE LAW

Surgeon's Fee Reduced by Court

In a suit by an orthopedic surgeon against an insurance company to recover a fee of $4,325 for services rendered in treating a patient's arm, a trial court did not err in awarding only $1,275. There was sufficient evidence to support a finding that that amount was a reasonable fee in the case, a Louisiana intermediate appellate court ruled. The patient's arm was severely injured when it was struck by the propeller of a motorboat.

The orthopedic surgeon testified that he considered that his charge was entirely reasonable and he was corroborated in this by another orthopedic surgeon. Two other experienced orthopedic surgeons from the same area testified for the insurer. They stated, respectively, that $600 and $1,000 would have been reasonable charges for the services rendered in this case. The law is well settled that whenever a doctor's charge is contested as being unreasonable and excessive, it is within the province of a court to adjust it to conform to the charges prevalent in the area where the services were rendered. On the basis of the evidence presented, there was no palpable error in the trial court's finding that the orthopedic surgeon's charge was excessive, and its finding will, therefore, not be disturbed, the court said.

Conscience: an inner voice that warns us somebody is looking. — Mencken

Water Absorption

by Dog Intestinal Mucosa

ALI A. HAKIM, M.D.*
St. Paul, Minnesota

Much of the advance in our understanding of intestinal absorption has been gained in the past 15 years from the study of *in vitro* preparations. Nearly all such preparations, including that of Fisher and Parsons[1] (generally considered the first of the satisfactory ones), have employed as a membrane the entire intestinal wall of rodents (rat, hamster, guinea pig). In the present investigation, membranes consisting of only the mucosa (epithelium plus lamina propria) of the small or large intestine of the dog were used successfully for the first time in the study of absorption. This paper will describe some aspects of the findings of these *in vitro* investigations, particularly as they relate to current theories of the mechanism of water absorption by the intestines.

Views of the Mechanisms of Intestinal Absorption of Water

Isotonic Water Absorption

Two observations challenging explanation are (1) absorption of water from isotonic NaCl or Ringer solutions or even from the animals own serum placed in the lumen (isotonic water absorption), and (2) absorption of water from hypertonic NaCl solutions. These processes can occur in the absence of a luminal hydrostatic pressure. In the first of the above observations, water is transported without an osmotic pressure difference, whereas in the latter, water is moved against the direction of the osmotic force. There is general agreement that active transport (transport driven by metabolic energy) by the epithelial cells is operating here in some way; this conclusion is supported by the dependence of the above kinds of water movement on the availability of oxygen and glucose (at least *in vitro*) and its inhibition by metabolic poisons. The main point of controversy is whether (a) Na^+ or Cl^- or both are absorbed actively with water following passively, or (b) water is absorbed actively.

Absorption of Water from Hypertonic Sodium Chloride

The second of the above observations, the absorption of water from hypertonic solutions, would superficially appear to be sufficient evidence for the occurrence of active water absorption, since water is being moved from low to high activity; moreover, the rates of absorption of sodium and chloride ions from hypo-, iso-, and hypertonic sodium chloride solutions placed in the dog intestines have been found to be consistent with a model providing for simple bulk flow and diffusion[2] without invoking active transport of sodium chloride.

Nevertheless, the most widely held view is that isotonic water absorption is a result of active sodium chloride absorption. The transported sodium chloride is thought to produce local relative hypertonicity on the blood side of the absorbing membrane, thus creating an osmotic driving force for passive water movement. The same process is presumed to operate for water absorption elsewhere in the body, as from the proximal tubule or the gallbladder. The essential bases for this view, so far as the intestine is concerned, appear to be first, evidence for the ability of the intestine to carry out active Na^+ transport,[3] second, the dependence of *in vitro* isotonic water absorption on the presence of Na^+ in the lumen,[3,4] and third, the nature of the calculated composition of the absorbed fluid (absorbate) during isotonic absorption. The most frequently cited relevant papers concerning the latter point are those of Curran and Solomon.[5,6]

---

*From the Division of Urology, Ancker Hospital, St. Paul, Minnesota, and the Division of Urology and Department of Physiology, University of Minnesota Medical School, Minneapolis, Minnesota.

The question still remains as to how the theory of active sodium chloride absorption would account for water absorption from solutions as much as 100 mOsm/L hypertonic.[2] With an intact circulation, it is extremely unlikely that the required osmotic pressures could be maintained in the interstitial fluid of the villi. The answer given is exemplified by the two-membrane-in-series model proposed by Curran.[6] Space does not permit a detailed description of this idea. Suffice it to say that there is no theoretical difficulty, given the proper physical arrangements, in accounting for the observed water movement by active solute movement.

Water and Sodium Chloride Absorption by Dog Mucosal Membrane in Vitro

Results obtained on the isolated dog mucosal preparation will now be presented as they relate to the above discussion.

Method of Study

The surgical removal of the mucosal membrane, the apparatus employed for studying absorption, and conduct of the experiment have been previously described.[7] Figure 1 shows the membrane in the process of being stripped; Figure 2 shows a histological section of stripped mucosa. In brief, for the study of absorption, the membrane was tied

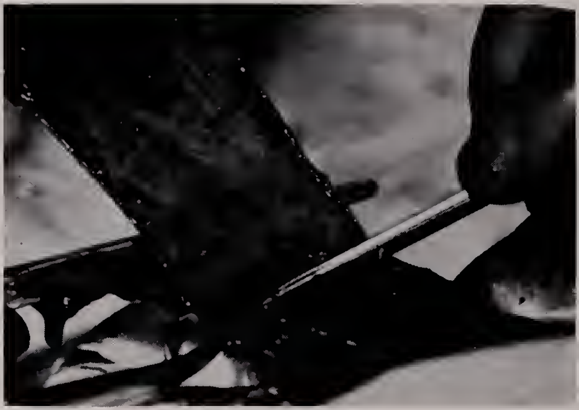

Fig. 1 — Dog mucosal membrane in process of being stripped.

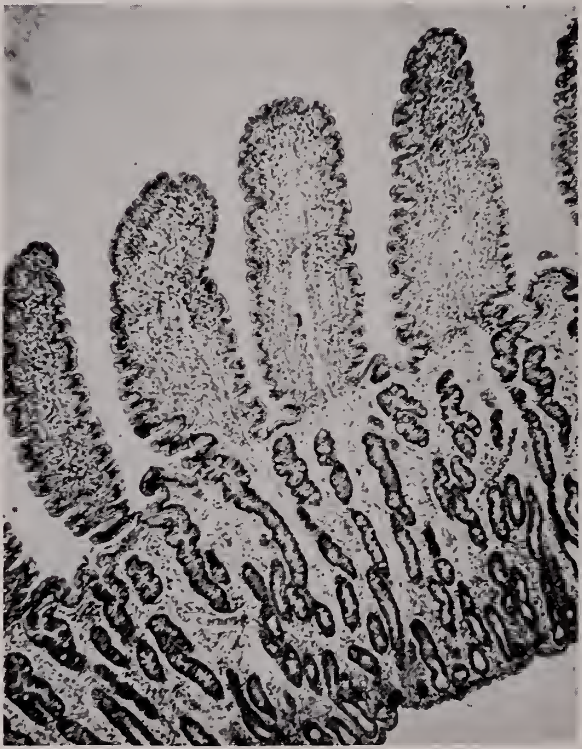

Fig. 2 — Histological section of stripped mucosa of small intestine.

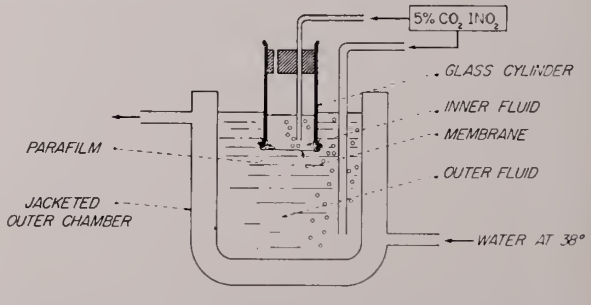

Fig. 3 — Arrangement for study of intestinal absorption.

on one end of a glass cylinder 6.4 cm^2 in cross sectional area, after which the membrane-covered end of the tube was immersed in a bathing fluid of large volume (about 200 ml.), as seen in Figure 3. Depending on the purpose of the experiment, the mucosal surface of the membrane faced either the large or small volume bathing fluid. The serosal bathing fluid was Krebs Bicarbonate Ringer, and all bathing fluids contained glucose. The Na^+ concentration in Krebs Bicarbonate Ringer was 146 mEq/L and the Cl^- concentration 127 mEq/L.

Water Absorption from Isotonic and Hypertonic Solutions

It was found that water was absorbed from isotonic Ringer fluid. The occurrence of this water absorption was largely dependent on the presence of glucose and oxygen in the medium, and it was prevented by suitable metabolic poisons. Furthermore, water was absorbed from Ringer fluids which were up to about twice isotonic. Transmucosal potential differences amounted to 5-13 mV, which is typical of other intestinal preparations *in vivo* and *in vitro*. It has been suggested that the electrical potential difference across the intestinal wall could provide the driving force for water transport by electro-osmosis.[4] However, the question would then arise as to the origin of the potential. It is usually attributed to active sodium transport.[3,8]

The above findings on this new *in vitro* intestinal preparation, supplemented by a number of others, such as active glucose transport and inhibition of water absorption by removal of Na^+ from the mucosal bathing fluid, provided evidence that it exhibited transport behavior expected of normal intestine.

Composition of the Absorbate

Representative data on the composition of the absorbate (Figure 4) show the relationship between sodium absorbed (J_{Na}) and water absorbed (J_w) from Ringer fluids, the osmotic activity of which was altered by changing their sodium chloride concentrations. The slopes represent the concentration of Na^+ in the water moved, corrected for solute movement which would occur with zero water movement. In each case, these slopes correspond to concentrations which were isosmotic with the luminal test solution (see legend of Figure 4). Similar results were obtained for Cl^-. The type of "coupling" between water and salt absorption is thus seen to be the same as has been reported *in vivo* for the intestine[2] and *in vivo* and *in vitro* for other absorbing organs, including the gallbladder.[9-11] The observations frequently considered more pertinent to the fundamental question of primary water versus primary sodium chloride absorption are those for the composition of the absorbate when a poorly absorbable solute osmotically replaces an appreciable portion of the Na^+, Cl^-, or sodium chloride of the Ringer fluids. Under such conditions, one or both of the ions, if absorbed, would be moved uphill. This leads us to the consideration of the phenomena of Cl^- and Na^+ impoverishment.

Impoverishment Phenomena

Chloride impoverishment by the intestine

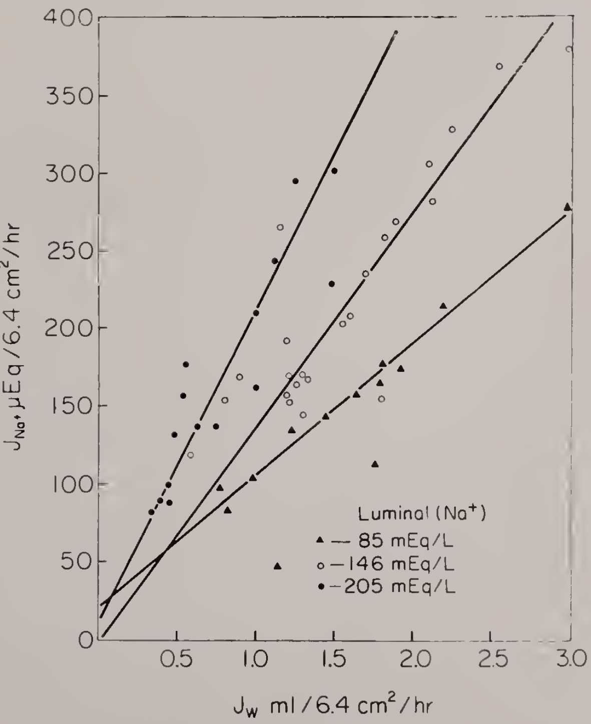

Fig. 4 — Relationship between absorption of sodium and water from Krebs Bicarbonate Ringer fluids, of varying sodium chloride concentrations. The lines have been visually fitted to the points. The slope of the lines are *83*, *130*, and *185* mEq/L respectively for the 85, 146, and 205 mEq/L luminal solutions.

refers to more rapid absorption of chloride relative to water from isotonic fluids with a chloride concentration less than that of the plasma. Typically, it has been studied in the dog from solutions ½ isotonic with respect to sodium chloride and Na_2SO_4 (the $SO_4^=$ being slowly absorbed relative to Cl^-). In the small intestine, it occurs most prominently in the ileum.[12] It has also been found *in vivo* in the rat and rabbit,[13] as well as in the dog.[12]

Sodium Impoverishment

Conversely, the analogous phenomenon, sodium impoverishment, occurs when $MgCl_2$ is used instead of the Na_2SO_4, and both Na and Cl impoverishment are found when a poorly absorbed nonelectrolyte replaces sodium chloride.[5,6] All the above *in vivo* impoverishment behavior was found to be exhibited in our *in vitro* preparation.

With respect to the composition of the absorbate during these various types of impoverishment experiments, the following observations were made. From solutions ½ isosmotic with respect to both sodium chloride and Na_2SO_4, the chloride absorbed was closely correlated with the water absorbed. For membranes taken from the lower 20% of the jejunum-ileum, as shown in Figure 5, the relationship appears to be reasonably linear, and the line fitted to these points has a nearly zero intercept. The slope of the line (the apparent Cl^- concentration in the fluid absorbed) is about 120 mEq/L and close to the Cl^- concentration in Krebs Bicarbonate Ringer. Thus, the 120 mEq/L in the solution moved originated from a luminal Cl^- concentration much lower in Cl^- (68 mEq/L). The Na^+ concentration in the absorbate was 160 mEq/L as compared with a luminal concentration of 190 mEq/L. The absorbate thus approximated an isotonic Krebs Bicarbonate Ringer fluid.

From ½ isotonic sodium chloride + ½ isotonic $MgCl_2$, despite the reverse situation with regard to luminal concentrations of Na^+ and Cl^-, the absorbate nevertheless again contained 160 mEq/L Na^+. The Cl^- concentration was somewhat higher, 148 mEq/L, than in the previous case. From ½ isotonic sodium chloride + ½ isotonic mannitol (Na^+ about 90 mEq/L and Cl^- about 68 mEq/L), with both ions moving against their concentration differences, the absorbate contained Na^+ = 142 mEq/L and Cl^- = 110 mE/L. Thus, in all these instances in which the luminal solutions were isotonic, the absorbate resembled isotonic Ringer fluid. These results are essentially the same as those on which Curran based his inference of primary active salt transport and secondary passive water transport.

Although the theories which postulate primary active water transport are not excluded by these findings, it is difficult to see how they can account for these phenomena in a simple way. In their conventional forms, these theories postulate either vesicular transport or some kind of fluid circuit, and both of these mechanisms would require rather demanding selective permeability properties for sodium chloride and other solutes. Therefore, if primary active sodium chloride and water transport are considered as mutually exclusive explanations of intestinal water absorption, active sodium chloride transport appears, in my opinion, to be the more likely one. It may of course turn out that contributions by active transport of both

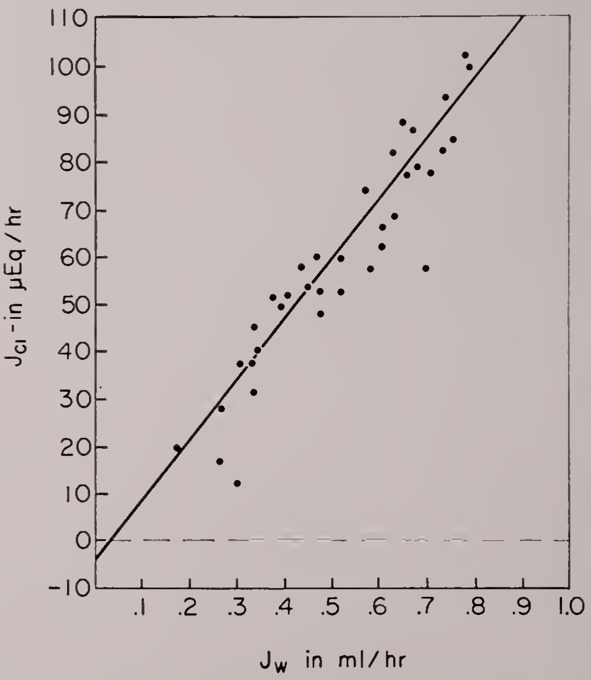

Fig. 5 — Relationship between absorption of chloride and water during the process of chloride impoverishment. The mucosal fluid was ½ isotonic sodium chloride + ½ isotonic Na_2SO_4.

are involved. In any event, the problem remains a fundamental one in the physiology of the intestine.

Importance of Convection in Intestinal Absorption

It is noteworthy that both of the contrasted theories imply a potential convective component in the absorption of any molecule. This component should appear most clearly in the case of small nonelectrolytes of low lipoid solubility for which the intestine has no special or active transport mechanisms.

The acceptance of the existence and importance of convective transport across cell and cellular sheet membranes has been largely due to Ussing; however, the evidence for its importance in intestinal absorption is relatively meagre. Among the most relevant investigations is that of Fisher,[14] who found that water movement and that of certain passively handled solutes were positively correlated. He concluded that such a process "as this coupled absorption must be the basis for absorption of the majority of drugs and foodstuffs, and (that) it may be supposed that physiological and pathological factors which affect water absorption will equally affect the absorption of this large class of solutes." In the literature, it is frequently assumed that the absorption of these substances is only by diffusion.

We studied this problem in great detail using urea,[15] D_2O,[15] thiourea, xylose, and antipyrine either *in vivo* or *in vitro* or both. We found that the convective component in the transport of these passively absorbed substances indeed had a dominating influence on the kinetics of solute movement during high rates of water absorption. This component manifested itself in an obvious way by causing absorption of these solutes against their concentration gradient, that is, in the direction opposite from that expected by diffusion.

Summary

The findings with this new preparation supplement those obtained on other preparations, which are viewed as favoring the theory that water absorption from isotonic or hypertonic solutions is passive and secondary to active sodium chloride absorption.

Findings are briefly described confirming the implication of the theories of water absorption that passive absorption of solutes should be in part convective.

The above work was performed in the Department of Physiology of the University of Minnesota Medical School in collaboration with Professor N. Lifson.

Pseudocysts

JOHN F. PERRY, JR., M.D., Ph.D.*
JAMES W. LAFAVE, M.D.*
St. Paul, Minnesota

ALTHOUGH PSEUDOCYSTS of the pancreas are not common lesions, they are the source of prolonged morbidity and possibly even death if not properly treated. For this reason the nature of these lesions and the techniques available for their treatment are worthy of review. In the discussion to follow pseudocysts are considered collections of necrotic tissue, blood and pancreatic juice in the lesser sac of the peritoneal cavity occurring as sequelae of pancreatitis or pancreatic trauma. False cysts due to other causes and true cysts or cystic tumors of pancreas will not be considered.

There may be a history of pancreatitis or blunt abdominal trauma followed within a period of weeks to months by the appearance of a slowly enlarging mass in the left upper part of the abdomen. In some patients no antecedent history of pancreatic inflammation or trauma can be elicited. Symptoms related to pressure on the stomach or gastric outlet obstruction may be present or the mass may be symptomless. Laboratory studies are usually not helpful. Radiographic examinations with and without contrast media demonstrate a mass displacing the stomach anteriorly; often the colon is displaced downward (Figures 1 & 2). With a clear-cut history of antecedent blunt trauma or pancreatitis the diagnosis is fairly obvious. In the absence of such a history it is possible only

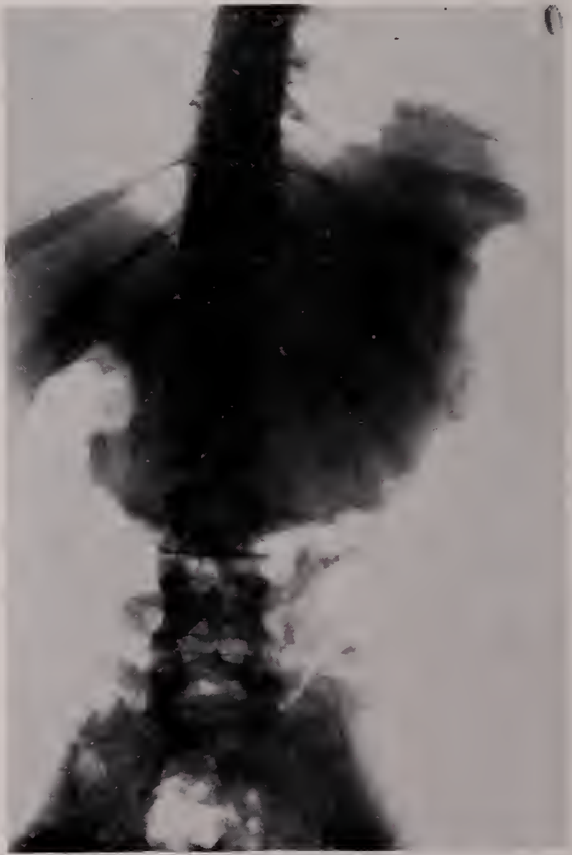

Fig. 1 — Supine radiograph showing mass in left upper quadrant.

of the Pancreas

to suspect such a lesion.

Surgical exploration is indicated. Gross appearance of a pseudocyst at operation is characteristic. There is a fluid-filled mass palpable behind the stomach, but attempts to approach the mass are met by dense adherence of visceral structures on all sides. The mass may lie predominantly in the upper or lower part of the lesser bursa, and part of the lesser sac may be obliterated. Location of the mass in part determines its proper treatment. Wall of the cystic structure consists of the surrounding stomach, pancreas, transverse colon and omentum, and it is obvious that such a structure cannot be excised. It is important that the true character of the lesion be recognized and its benign character established by (1) its characteristic location, (2) aspiration which demonstrates a brown muddy fluid consisting of necrotic tissue, blood and pancreatic juice, and (3) biopsy of the wall at the site decided upon for drainage. Once it has been entered, the wall of the false cyst will be found to consist of fibrous tissue, fibrin and a coagulum of digested blood applied to visceral strictures. On entering the cyst with other than an aspirating needle care must be taken to avoid opening the stomach, colon or small bowel which are adherent to it. It is usually possible to reflect the omentum from the transverse colon sufficiently for aspiration and determination of the proper site for draining the pseudocyst.

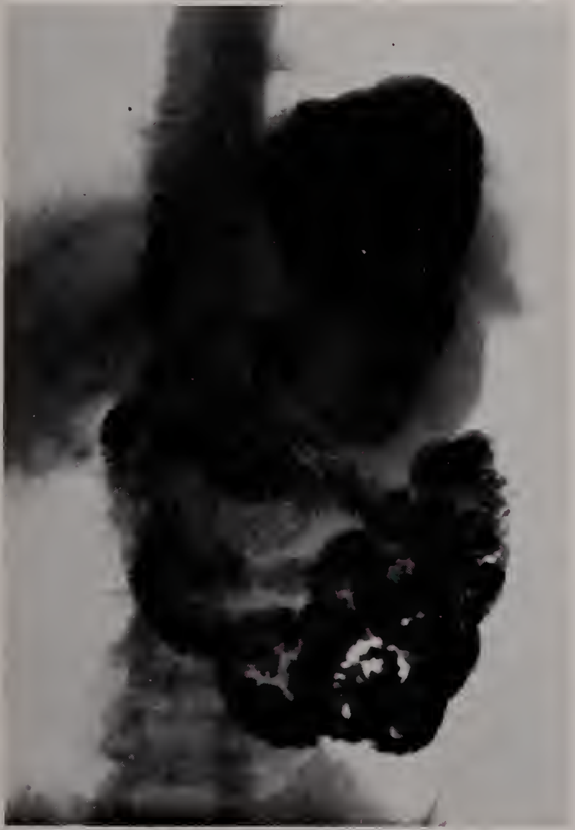

Fig. 2 — Upper gastrointestinal study with barium showing stomach displaced anteriorly by a mass.

Surgical Procedures for Treatment of Pseudocysts

Techniques employed for management of pseudocysts are given in Tables 1 and 2, and the advantages and disadvantages of each will be briefly discussed.

Marsupialization and External Drainage*

First described in 1883 by Gussenbauer,[1] variations of this technique remained the standard method of treatment for many years. Some pseudocysts communicate with the pancreatic duct system by large openings; in others the accumulation in the lesser sac has come from much smaller communications. If pseudocysts have the former type of communication or if there is obstruction in the pancreatic ducts, prolonged drainage, cyst recurrence, excoriation of skin and electrolyte imbalance have occurred. Reoperation has been necessary in one fourth of the cases.[2] For cysts with small communications and no duct obstruction, closure can be expected with external drainage, since pancreatic secretions do not continue to be poured into the cyst. Unfortunately, without pancreatography it is not possible to demonstrate which cysts have functional communications and which do not. Since there are more satisfactory techniques for dealing with pseudocysts, external drainage alone is no longer an acceptable operation.

Cystgastrostomy

Cystgastrostomy with resection of part of the cyst represented the earliest effort at internal drainage.[3] An improvement was cystgastrostomy by a transgastric approach.[4] In this latter operation an incision is made in the anterior wall of the stomach, and that portion of the posterior gastric wall which overlies the pseudocyst is incised and the cyst opened. A running suture for hemostasis is placed around the opening in the posterior gastric wall, and the anterior wall of the stomach is closed in layers. This operation has many advocates, but a few authors have condemned it because of passage of gastric contents into the cyst,[5,6] with resulting pancreatitis[6] and hemorrhage.[7,8] Cystgastrostomy may be useful for those cysts lying high in the lesser bursa which are not easily accessible for drainage into the small bowel.

Cystduodenostomy[9]

For pseudocysts which present anterior to the head of the pancreas, anastomosis has been constructed between the cyst wall and duodenum. Such a procedure is advantageous if a fistula from the pancreatic duct persists so that pancreatic juice drains into the duodenum. A theoretical disadvantage of the operation is regurgitation of gastric juice, food and bile into the cyst. The operation would appear to have a very limited role in the treatment of pseudocyst.

Cystjejunostomy

Anastomosis of the cyst to the jejunum has been accomplished by several methods: simple cystjejunostomy,[10] cystjejunostomy with jejunojejunostomy,[11] transvisceral cystenterostomy,[12] cystjejunostomy Roux-en-Y,[13]

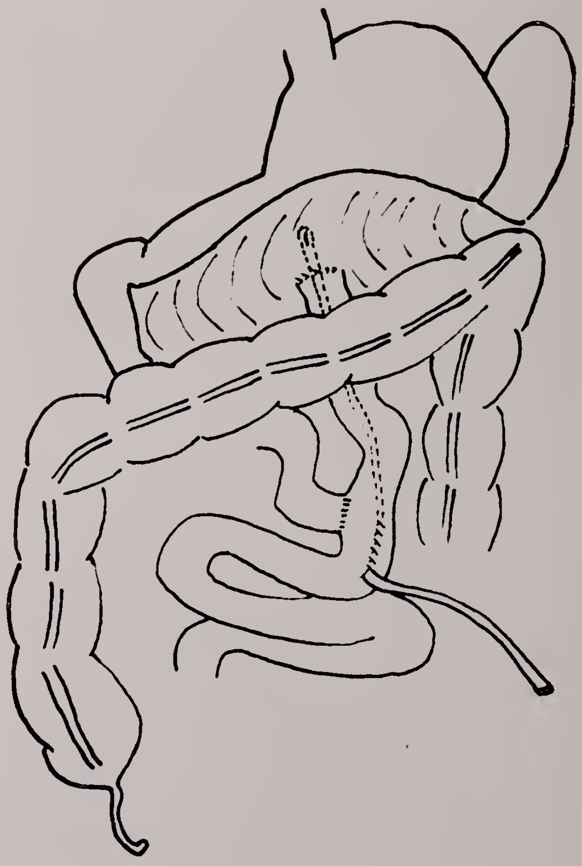

Fig. 3 — Modification of Roux-en-Y cystenterostomy by addition of catheter enterostomy.

---

[*] See Test Your Word Score Page 1491.

and cystjejunostomy Roux-en-Y with catheter enterostomy.[14]

Simple cyst jejunostomy would seem to have the same disadvantages as cystgastrostomy, namely, that intestinal contents would enter the cyst cavity. In a collected series of 32 patients in whom simple cystjejunostomy had been used, Warren and associates[2] found that five deaths (15.6%) occurred and two reoperations were required.

Transvisceral cystenterostomy has been utilized when the small bowel forms part of the cyst wall at some point. Drainage is accomplished by opening the intestine, then creating a stoma between cyst and bowel at the point of adherence, followed by closure of the bowel. Regurgitation will occur after this operation, and it appears there will be few circumstances when adherent intestine can be utilized in this manner to drain a pseudocyst.

Cystjejunostomy Roux-en-Y has been extensively employed.[2] The advantage of this operation or of cystjejunostomy with jejunojejunostomy lies in a provision for keeping intestinal content away from the cyst cavity. In a series of 46 cases there was an over-all 2.2% mortality rate, and two reoperations were necessary.[2] Breakdown of anastomosis,[2] intestinal hemorrhage[15] and recurrent cyst[15] are complications which have been attributed to this procedure. Shumacker[16] in 1954 reported five patients treated by this procedure and found a total of 17 cases in which the operation had been performed successfully.

We have modified this procedure by addition of catheter enterostomy. By external drainage through the catheter it is possible to keep the cyst decompressed until firm union has occurred between cyst wall and jejunum. The catheter enterostomy poses no problem and in addition allows assessment of cyst size by instillation of radio-opaque media at intervals until the cavity is obliterated when the enterostomy tube is removed. In those cysts which close without a permanent fistula it will be necessary to determine whether the blind loop created by Roux-en-Y drainage procedure is associated with any of the complications which have been attributed to blind intestinal loops under other circumstances.

Implantation of Fistula into Jejunum after External Drainage[17]

Application of this operation is limited to patients previously treated by external drainage with a persistent external pancreatic fistula. Under these circumstances it may be possible to amputate the fistulous tract as close to the body of the pancreas as possible and anastomose it to the jejunum. For external fistulas, some direct attack on the pancreatic duct system as described below is probably better.

Sphincterotomy with Concomitant External Drainage[17]

Advocates of this procedure have concluded that patients with pseudocysts of inflammatory origin have spasm of the sphincter of Oddi which tends to perpetuate or increase the size of the cyst. Drainage would be expected to persist because spasm causes pancreatic intraductal pressure to be higher than normal. Sphincterotomy was proposed not only in treatment of the inflammatory cyst but to prevent recurrent pancreatitis. The demonstration that obstructions in the pancreatic duct in pancreatitis are often multiple and not limited to the sphincter of Oddi indicates such an approach is not applicable in all patients with pseudocyst. Before treatment of pseudocyst by sphincterotomy and external drainage it would be necessary to demon-

strate by radiographic visualization of the pancreatic duct a definite communication between cyst and duct and no obstructions of the duct. If these criteria are met the concept appears sound in principle.

Retrograde Transductal Internal Drainage

Menguay and Blalock[18] have reported a patient with a pseudocyst lying over the head of the pancreas and behind the antrum and the first portion of duodenum who was treated by amputation of the tip of the tail of the pancreas, by opening of the pancreatic duct, and by creation of a large stoma between cyst and duct by an instrument introduced into the cyst through the duct. The tail of the pancreas was then anastomosed to a Roux-en-Y loop of jejunum. Such an operation for draining the cyst into the pancreatic duct would be applicable only to those pseudocysts overlying the pancreatic head. It would appear to be a more difficult operation than others.

Discussion

In patients with pseudocyst of inflammatory or traumatic origin internal drainage is preferable to external. A number of operations have been proposed to accomplish internal drainage. Basically they fall into two general categories: (1) Those procedures wherein the cyst is anastomosed to the gastrointestinal tract. No direct attack is made upon the pancreas itself, and if a fistula from the pancreatic ductal system persists, secretions will enter the alimentary canal. Such an approach does nothing for the underlying pancreatic disease in the case of post-inflammatory pseudocyst and recurrent cyst formation and pancreatitis after cyst enteric anastomoses have been described.[17] (2) Procedures designed to drain the pseudocyst into the pancreatic duct. Operations such as those described by Doubilet and Mulholland[17] and Menguay and Blalock[18] fall into this category. Provided the possibility of multiple sites of occlusion in the duct system is considered, the basic principle of such procedures is sound. Unless at least a part of the pancreas and its ductal system is accessible and unless the surgeon is skilled in such operations, cyst enteric drainage is probably the preferred approach. Except under a few circumstances mentioned before, cystjejunostomy Roux-en-Y is probably the operation most likely to give a satisfactory result.

Hematuria
in
Sickle
Cell
Disease

BOYD SHOOK, M.D.*
HAROLD WINDSCHITL, M.D.*
St. Paul, Minnesota

HEMATURIA OCCURRING in patients with sickle cell disease was first reported in 1948. Although many cases have now been reported, general awareness of this phenomenon has been poor. At Ancker Hospital we recently encountered a patient who pointed up this problem; and although the negro population of St. Paul and Ramsey County is small, the diagnosis of sickle cell hemoglobinopathy has been made in 62 patients during the last five years. In all instances the diagnosis was based on either positive sickling preparations or hemoglobin electrophoresis. A review of these 62 patients has revealed eight with gross hematuria for which there was no other explanation. Four of these patients will be presented in some detail.

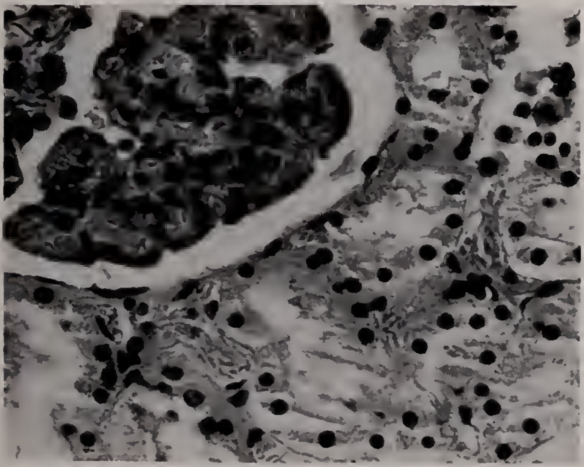

Fig. 1 — Post-mortem histology of kidney showing intense congestion and sickling of erythrocytes. (x600)

Case Reports

Case 1.

An 18-year-old negro male entered Ancker Hospital because of painless gross hematuria which began following a wrestling match. He denied severe bruises but did relate minor flank trauma during the bout. He was not anemic. Urinalysis was normal except for gross blood. Multiple studies for renal disease were negative. Cystoscopy demonstrated bloody efflux from the left ureter. An intravenous pyelogram was normal except for clots in the renal pelvis. Cultures of the urine for routine pathogens, Mycobacteria, and fungi were negative. Bleeding and clotting studies, vascular fragility, and platelet counts were normal. A sickle cell preparation was positive, and electrophoresis of his hemoglobin solution demonstrated S and A hemoglobins. Treatment was conservative and bleeding ceased after 36 days.

Case 2.

A 49-year-old negro female began to pass bright red blood per urethra during an episode of bronchitis. She stated that a previous similar episode had occurred in 1940. She was told then that she had a tumor in her left kidney, but no surgery was done. Cystoscopy demonstrated brisk bleeding from the left ureter. An intravenous pyelogram revealed a mass in the left renal pelvis which was felt to be either a tumor or blood clots. Cultures were negative. She was not anemic. A sickle cell preparation was positive, and electrophoresis of her hemoglobin demonstrated a mixture of S and A hemoglobins. Bleeding ceased after 10 days of bed rest. Subsequent pyelograms have been normal.

Case 3.

A 53-year-old negro male began passing gross blood per urethra one week after the onset of pneumonia. He was not anemic. Urinalysis was normal except for blood. A sickle cell preparation was positive, and electrophoresis demonstrated S and A hemoglobins. As he ceased bleeding after three days, no further studies were undertaken. A subsequent intravenous pyelogram was normal. He died one month later of a myocardial infarction. Post-mortem examination revealed only congestion of his kidneys with sickled erythrocytes in the renal vessels (Figure 1).

---

*Section of Hematology, Division of Internal Medicine, Ancker Hospital.

Case 4.

A 37-year-old negro female is the mother of nine children, including seven children with sickle cell hemoglobinopathy. She is not anemic but has been seen in the Ancker Receiving Room on multiple occasions complaining of arthralgia and abdominal pain. She is alleged to imbibe to considerable excess and for prolonged periods of time. During one such episode of ethanolic* debauchery she began to pass red blood in her urine. This continued for three weeks, at which time she was admitted to Ancker Hospital. Bleeding ceased shortly after admission. Cystoscopy was performed but no bleeding site could be localized. Studies for infection were negative. An intravenous pyelogram was normal. A sickle cell preparation was positive and electrophoresis demonstrated a mixture of S and A hemoglobins.

A summary of our eight patients is presented in Table 1. The ages range from 18 to 54 years. There are four females and four males. Hemoglobin electrophoresis has been performed in five, all of whom have SA hemoglobin. Bleeding was localized in two instances, both from the left ureter. Duration of bleeding was variable but stopped in each instance without surgical intervention. Of particular interest is the fact that many of these patients had some event that could conceivably have precipitated a crisis of in vivo sickling. It is well known that patients with SA hemoglobin may have considerable difficulty if the oxygen tension of their blood is lowered or if stasis occurs in their venous system. Thus it may be significant that hematuria occurs following bronchitis, pneumonia, smoke inhalation, congestive heart failure, or even the sound slumber following the ingestion of large amounts of spiritus frumenti.*

Review of Literature

Shortly after Abel and Brown[1] reported hematuria in a young negro soldier with sickle cell disease, other cases began to be recognized and reported. It became apparent that this was not an uncommon manifestation of sickle cell disease. There have been 152 cases reported in varying detail.[1-16] Table 2 is a summary of these patients who were reported in sufficient detail for tabulation.

Electrophoretic analysis of hemoglobin solution was performed in 76 patients. Of these, 54 had SA hemoglobin, 21 had SC hemoglobin, one patient had sickle cell thalassemia and one SS hemoglobin. When these figures are compared with the frequency of each hemoglobin type, there is a slight preponderance of SA and SC hemoglobin types. No reason is apparent for this preponderance.

Of particular interest is the site of bleeding in these patients. Bleeding was localized in 113 patients. Of these, 77 bled from the left kidney, 32 bled from the right, and four bled from both kidneys. This represents a significant difference for which there is no physiologic explanation. It is of interest that early reports were of bleeding from the left side, while later reports are of bleeding from the right side. Perhaps future reports will effect a balance between right and left.

Sex was identified in 136 patients. There were 86 males and 50 females. Recent reports show females in predominance, so that a balance may be achieved here as well as in location. A reasonable explanation for these variations may be that early reports were almost exclusively from the Armed Forces. In this situation the cases would be selected from young adult males who were healthy enough to be inducted.

Duration of bleeding is highly variable. Most patients bleed only a few days, but some are reported who have bled almost continuously for over 10 years. The average duration is two to three months. Intermittent bleeding is common, and recurrences are almost universal. One patient had severe bleeding, recovered, and then had a recurrence 30 years later.

---

*See Test Your Word Score Page 1491.

The age at the time of bleeding ranges from five to 70 years, with a sharp peak between ages 25 and 35.

Pathogenesis

Sickle cell disease may be divided into several categories on the basis of electrophoresis and chromatography of hemoglobin solutions. The severity of anemia and frequency of crisis correlates roughly with the per cent of S hemoglobin present. Most patients with SA hemoglobin have less than 50% S hemoglobin and have very little, if any, trouble. However, under conditions of decreased oxygen tension they do have difficulty. They may, for example, have a typical crisis following high altitude flight.[17]

The phenomenon of hematuria does not follow the usual guidelines. In the earlier reports, a large majority of patients with hematuria began bleeding following a long march or minor flank trauma. Later reports have emphasized bronchitis, pneumonia and congestive heart failure as precipitating events. One of our patients, a fireman, began to bleed following smoke inhalation.

Anatomic study of the kidneys is not helpful in terms of etiology.[18,19] There is congestion of vessels with sickled erythrocytes and erosion of the pelvic mucosa. Rarely is papillary necrosis seen.

Renal physiologic studies in patients with sickle cell disease demonstrate increased glomerular filtration rate, effective renal blood flow, and tubular excretory capacity.[20] In addition, there is some impairment of concentrating ability, so that hyposthenuria* is common.[21] However, these aberrations do not explain why bleeding begins. The oxygen tension in renal capillaries is low enough to favor sickling. Presumably, every patient with sickle cell disease has sickled erythrocytes in renal capillaries. A reasonable hypothesis is that this physiologic state favoring sickling, when coupled with trauma or con-

gestion, initiates a vicious cycle of stasis and sickling resulting in hematuria.

Treatment

There is no specific treatment for sickle cell disease. Many therapeutic modalities have been employed with no success. Oxygen does not appear to be effective but is still used in an effort to reduce sickling. Hematuria associated with sickle cell disease almost always stops spontaneously. Nephrectomies were done a few years ago but were usually followed by bleeding from the other kidney. Bed rest and transfusions as necessary seem to offer the best approach to this problem. Since recurrences are common, nephrectomy should be avoided at all cost.

Summary

Hematuria, associated with sickle cell disease, is not uncommon. During the last five years, eight patients with this syndrome have been seen at Ancker Hospital.

There have been 152 cases reported in the literature. There is a preponderance of SA and SC hemoglobin in these patients. Bleeding may recur several times or may be persistent for years. Reports show a predominance of males with bleeding from the left side.

The etiology of hematuria in patients with sickle cell disease is unknown.

Treatment should be conservative since bleeding tends to stop spontaneously and may recur after nephrectomy.

PANCREATIC MALIGNANCY SYNDROME

This syndrome presents a diagnostic triad of (1) progressive obstructive icterus; (2) large palpable gallbladder (Courvoisier's sign*), and (3) rapid, progressive cachexia.

Anorexia, rapid weight loss and night pain are the usual symptoms. A decrease in the enzyme concentration in the duodenum results in an impairment of glucose metabolism with hyperglycemia and a marked increase of neutral fat in the stool. Serum lipase is increased and the serum bilirubin becomes elevated. A barium X ray may show a widened duodenal loop, and multiple venous thrombophlebitis migrans is a common complaint. The course is rapid and the outcome fatal, with a poor prognosis from surgery.

Fiction is a beguiling wench for the bewildering roulette of life. — Lea Rosten

Trepopnea[*] a Possible Cause for Unilateral

WHILE THE radiographic picture of pulmonary edema is usually that of ill-defined confluent mottled shadows which fan symmetrically from both hila and spare the periphery of the lung,[1] pulmonary vascular congestion may appear as unilobar, multilobar, nodular or miliary infiltrations which simulate metastatic or primary malignancy, bronchiectasis, pneumonia, tuberculosis, uremic pneumonitis or pulmonary infarction.[2-8] The purpose of this report is to present a case of pulmonary edema which was radiographically confined to the right thorax and to comment on a possible cause.

Case Report

An 85-year-old white woman, was admitted to D. C. General Hospital on February 2, 1963, because of shortness of breath.

Past History

The patient had been without known heart disease until 17 years prior to admission when she was admitted to another hospital because of a "heart attack" and a "slight stroke," which were manifested by ill-defined chest pain and transient hemiparesis respectively. Since that hospital admission she had had orthopnea, slight dyspnea on exertion, and occasional substernal chest pain relieved by nitroglycerine. *For an unknown period of time she was unable to lie on her left side because of dyspnea incurred in that position.*

For the two years preceding admission, she had been confined to a nursing home because of blindness and inability to care for herself and, therefore, spent much of her time at bedrest and on her right side.

Present Illness

Two weeks prior to admission the patient developed an upper respiratory infection characterized by coryza and cough productive of whitish nonfoul-smelling, but occasionally blood-flecked sputum. Concomitantly she noticed progressive shortness of breath and frank episodes of paroxysmal nocturnal dyspnea. For the two nights prior to admission she had been unable to sleep at all because of dyspnea and wheezing. A roentgenogram taken on admission was read as compatible with right upper lobe pneumonia or tuberculosis. There was no history of chills, fever, hypertension, pleuritic chest pain, anorexia, nausea, or vomiting.

Physical Findings

Physical examination on admission revealed an elderly, alert white woman in moderate respiratory distress lying on her right side. Blood pressure was 130/90, pulse 90 and irregular, temperature 98.6 and respirations 28. Bilateral corneal opacities were present. The neck veins were distended at thirty degrees and filled from below. The right chest revealed inspiratory crackling rales to the level of the scapula and scattered expiratory rhonchi at the right base, while the left chest was relatively clear. On auscultation of the heart, an irregularly irregular rhythm and a ventricular diastolic gallop were heard, with the aortic component of the second sound louder than the pulmonic. A grade II systolic murmur was heard at the apex which radiated to the left sternal border. Examination of the abdomen revealed a positive hepatojugular reflux and a smooth, nontender liver palpable three fingers below the right

LAWRENCE V. PERLMAN, M.D.**
New Haven, Connecticut

Pulmonary Edema

costal margin in the midclavicular line. There was no peripheral edema, clubbing or cyanosis.

Laboratory Findings

The admission laboratory data revealed a hematocrit of 49, a white blood cell count of 7700 per cu. mm. with a normal differential count, and a urine with a specific gravity of 1.018 and two to three white cells per high power field. The fasting blood sugar was 85 mgm. %, and the blood urea nitrogen 40 mgm. %, the latter falling to 14 mgm. % at the time of discharge. The electrocardiogram showed atrial fibrillation. The admission chest roentgenogram showed cardiomegaly and a mottled shadow fanning out from the right hilum and involving most of the right hemithorax (Figure 1a). Tuberculin and histoplasmin skin tests were negative. Sputum smear was unremarkable, while sputum culture grew Neisseria catarrhalis and alpha hemolytic streptococci. Three twenty-four hour sputum specimens showed no tubercle bacilli.

Treatment

The patient was treated with digoxin and Mercurhydrin.[c] Twenty-four hours after admission she had lost three pounds and was no longer dyspneic. A chest roentgenogram on the third hospital day showed almost complete clearing of the right-side infiltration (Figure 1b). Her cough and coryza cleared, and she remained afebrile during her hospital stay. She lost a total of six pounds and was discharged without symptoms on the fourteenth hospital day.

Discussion

The clinical diagnosis of unilateral pul-

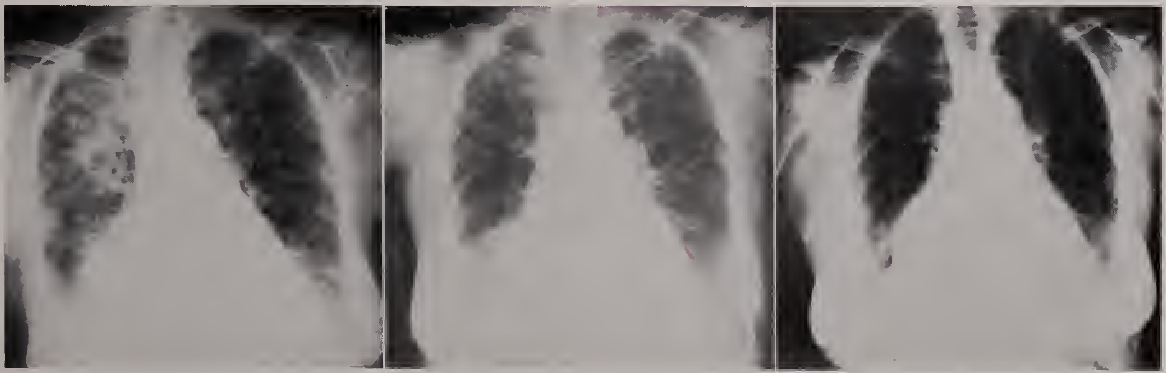

Fig. 1 — (left) Admission X-ray showing cardiomegaly and diffuse infiltration involving most of the right hemithorax. (middle) Follow-up film revealing almost complete clearing of the right-sided infiltration taken forty-eight hours after admission. (right) Film taken six days after admission showing complete clearing of right-sided shadow.

monary edema was substantiated in this patient by rapid roentgenographic clearing. Of the conditions which it may simulate, only pulmonary vascular congestion clears as rapidly. Moreover, the clearing was concomitant with the administration of a mercurial diuretic, and the patient had no findings (fever, positive sputum culture) suggestive of pneumonia. The degree of nitrogen retention was not at the level usually associated with uremic pneumonitis. Finally the majority of unilateral radiographic manifestations of pulmonary edema were confined to the right chest.[2-8]

It seems reasonable to assume that the patient's preference for the right lateral decubitus position played a major role in the radiographic localization of pulmonary edema in an individual confined to bed in a nursing home because of blindness. Increased hydrostatic pressure induced by gravity potentiates intra-alveolar extravasation of fluid in a manner analogous to the occurrence of pedal edema in dependent extremities.[9,10]

Right-sided preference, because of distressing symptoms incurred on the contralateral side, is not uncommon in individuals with congestive heart failure. In one study of 52 such patients, only two preferred sleeping on their left side.[11] This phenomenon is called trepopnea (literally, to turn to breathe). While the reason for it is unknown, right-sided preference appears to be correlated with anginal symptoms or dyspnea incurred on the left side.[11]

Although developmental variations in pulmonary structure, differences in pulmonary lymphatic and venous drainage, and pulmonary tissue resistance may explain the localization of pulmonary edema in certain instances, the position a patient assumes in bed should also be considered an important factor.[12]

Conclusion

A patient with unilateral pulmonary edema was found to have a preference for lying on her right side because of distressing symptoms when she lay on her left. No other cause for the localization of pulmonary edema could be identified. The position a patient assumes in bed may therefore be an important factor in the localization of intrapulmonary fluid.

Famous Prefaces

Do but take care to express yourself in a plain, easy Manner, in well-chosen, significant, and decent Terms, and to give a harmonious Turn to your periods; study to explain your Thoughts, and set them in the truest light, laboring as much as possible not to leave them dark or intricate, but clear and intelligible.

— Cervantes — Preface to Don Quixote

A Practical Approach to the Patient with Seizures

ROBERT J. GUMNIT, M.D.*
St. Paul, Minnesota

A SEIZURE especially a generalized grand mal attack, is one of the most dramatic symptoms of central nervous system dysfunction. Often a physician without a special interest in neurological disorders must treat a patient with seizures, perhaps on an emergency basis or as part of a family practice. This paper proposes to supplement the exhaustive details of the neurology textbooks with some practical advice.

A seizure is a symptom, not a disease. Any person is capable of having a seizure; thus not all patients with seizures have epilepsy. The term epilepsy, incidently, is no more specific than the term "crippled." It merely refers to patients with recurrent seizures and implies nothing about etiology. The chief problem facing the physician is to determine if the seizure is a symptom of a disease requiring specific therapy, or if it is a symptom of a chronic seizure disorder. Although the great majority of seizures occur in epileptics, many, if not most of the patients who have had one seizure or more, are not suffering from epilepsy. The epileptic carries an enormous social and legal burden. One should, therefore, hesitate before diagnosing any patient as an epileptic, reserving the term for those who have had more than one seizure not clearly related to a temporary condition.

The Emergency Treatment of Seizures

As a general rule a seizure, even the most severe grand mal attack, is a self-limited process. More than one general practitioner has learned to hitch up his horse slowly. By the time he arrived at the patient's house, the seizure was over. Repetitive seizures, however, especially repetitive grand mal attacks (so-called status epilepticus) are life-threatening. The patient must receive immediate treatment. The risks of status epilepticus are essentially those of respiratory embarrassment. There are many factors involved: obstruction, aspiration, prolonged apnea, and the increased energy demand and diffuse brain swelling accompanying repetitive seizures.

Stop the Seizures

In general, the safest and most effective means of stopping repetitive seizures is the slow intravenous administration of sodium amobarbital (Amytal®). Keep giving the drug until the seizure ends, but try to stop short of full anesthesia if possible. This form of treatment is, literally, the induction of general anesthesia with a short-acting barbiturate. Although amobarbital has no anticonvulsive action unrelated to its anesthetic effect (as phenobarbital has), it has the advantage of being short-acting and carries less risk of laryngospasm. Intravenous phenobarbital should be avoided because it takes 10 to 15 minutes to reach its full effect even with intravenous administration. As a result, overdosage is hard to avoid. Intramuscular phenobarbital in adequate dosage, at least

---

*Director, Division of Neurology, Ancker Hospital, Assistant Professor of Neurology, University of Minnesota.

100 mgm. for the average adult, is a very useful drug. Intravenous diphenylhydantoin (Dilantin®) carries a high degree of risk of central depression of respiratory and vasomotor control. Although it has been used successfully for the treatment of status epilepticus, unless one is expert, it is best to administer 100 mg. of Dilantin® intramuscularly. However, one should not rely solely on intramuscular Dilantin®. With intractable cases which do not respond to intravenous Amytal®, supplemented with intramuscular phenobarbital and Dilantin®, it may be necessary to use paraldehyde or to induce general anesthesia with ether.

Treat the Anesthetized Patient

When seizures are stopped in this manner, the physician must now deal with an anesthetized patient. It is absolutely essential that the airway be kept patent, that aspiration be avoided, and that artificial respiration be used if central depression of respiration has taken place. The blood pressure should be watched since the patient will frequently suffer impairment of cardiac and vasomotor function from the anesthetic, hypoxia and hypercapnia.†

Consider the possibility that the patient requires specific treatment for the cause of the seizure. One must always keep in mind the possibility that the seizure might have been caused by hypoglycemia or by anoxia secondary to impaired cardiorespiratory function.

Causative Factors

Temporary, Reversible Factors

Drug toxicity* or drug withdrawal** can cause seizures which need to be only temporarily controlled. Once the patient's metabolism has returned to normal, he will be free of the problem. Seizures accompanying high fever in children can also be included in this group.

Factors Requiring Specific Therapy

Acute infections (meningitis, encephalitis or brain abscess) are a frequent cause of seizures. Low-grade central nervous system infections such as syphilis, tuberculosis, and the fungal and parasitic infections may also produce seizures. Less common causes include hypovitaminosis (especially vitamins B-1 and B-6), hypothyroidism (in young children), hypocalcemia and hypoglycemia secondary to excessive insulin secretion. Electrolyte imbalance (in an extreme form, water intoxication) is a frequently overlooked cause.

A seizure may be a symptom arising from acute brain injury (trauma, subdural hematoma, intracerebral hemorrhage, subarachnoid hemorrhage, brain tumor) or acute cerebral vascular insufficiency (from stroke, myocardial infarction, cardiac arrhythmia or faint). The most common causes of seizures in elderly people are small strokes or other disturbances of cerebral circulation.

Epilepsy

There is a group of patients whose seizures are not amenable to specific medical or surgical therapy. Often we may know the cause of the seizure but not be in a position to do much about it. These patients, with chronic, repetitive seizures, make up the group that we commonly call "epileptics." They may be conveniently divided into two broad categories.

Symptomatic Seizures

These seizures are due to irritation by a lesion in the brain. Such irritation may be caused by scarring from an injury (accidental or neurosurgical), a brain tumor or a stroke. These changes are visible anatomically or pathologically. The most common cause of such seizures in the younger age group is injury suffered at birth. The temporal lobes, especially in the hippocampal† region, are notoriously susceptible to birth injury, and many of the large group of temporal lobe epileptics have seizures on this basis. Venous thrombosis will cause a scar leading to seizures and occurs especially in pregnant women.

The Clinical Forms of Symptomatic Seizures

a. Pure grand mal (generalized tonic-clonic seizures with immediate full loss of consciousness). A grand mal attack often occurs after any type of focal seizure.

---

*e.g. Phenothiazines, antihistamines, too much insulin.

**e.g. Alcohol, barbiturates, meprobamate or Librium.®

†See Test Your Word Score Page 1491.

b. Grand mal seizures preceded by aura. The aura is actually a focal sensory seizure which spreads to a generalized seizure.

c. Focal motor seizures, limited to one limb or one side, may occur with preservation of consciousness.

d. Jacksonian seizures: focal motor seizures which start in one portion of the body and then spread to involve the rest of the side in a "march" along the motor cortex. These are quite rare but very dramatic.

e. Psychomotor seizures. These are more complex and bizarre than any other. The layman does not easily recognize them as seizures, although they can usually be recognized by the knowledgeable observer. Clouding of consciousness, incoherent speech, and amnesia for the episode are typical.

The motor manifestations range from the involuntary performance of partially coordinated movements to complex, highly coordinated activity which is recognized as involuntary only because it is so inappropriate to the situation. The patient may walk about, become combative, unbutton his clothes, expose himself, perhaps engage in aimless searching. If spoken to, it is apparent that he is not conscious of his environment. If he replies, the response is often irrelevant. Particularly helpful in making the diagnosis are the presence of lip smacking, chewing movements, and other minor motor phenomena more easily recognized as ictal. The attack may culminate in a grand mal seizure, sleep, or a prolonged period of confusion.

Many patients with psychomotor seizures also suffer from temporal lobe disorders, but one cannot speak of the two phenomena as synonymous. Not only must more knowledge of brain physiology be obtained before reaching this conclusion, but prolonged petit mal lapses are often indistinguishable from psychomotor seizures.

Cryptogenic Seizures

Idiopathic or cryptogenic epilepsy characterizes the other large group of epileptics. As the name indicates, we really don't know why these patients have seizures. There is

TABLE I

Drug	Indications	Total Daily Dosage	Side Effects	Precautions
Phenobarbital	Grand mal Focal motor Psychomotor	45-300 (average 90) mg. In infants & children, 2-4 mg/kg/day.	Somnolence	May produce hyperactivity in children. Dangerous to patients with porphyria (who may present with szs.)
Diphenylhydantoin (Dilantin®) (Phenobarbital and Dilantin are commonly used together.)	Grand mal Focal motor Psychomotor	200-600 mg/day. Infants & children, 2-6 mg/kg/day.	Gastric distress Acne Hirsutism Gum hypertrophy (control with good hygiene & massage) Fatigue Restlessness-children Incoordination-gait Nystagmus & diplopia	Permanent cerebellar damage may result from prolonged overdosage. Rash with fever usually disappears after dose is lowered. Can be increased later. Blood dyscrasia is rare.
Primidon (Mysoline®)	Psychomotor Grand mal	0.5-2 grams/day. Infants & children up to ½ adult dose.	Nausea & vomiting Dizziness & vertigo Somnolence Psychic disturbance	Start with very small dose and increase gradually.
Ethosuxamide (Zarontin®)	Petit mal	Children 0.25 G.-1 G/day. Adults 0.5-2 G/day. Start with low dose.	Rare. Anorexia, fatigue, psychic upset Dizziness	May increase frequency of grand mal if used alone; rarely causes leukopenia or pancytopenia.

a definite, although slight, hereditary tendency in many of these cases. Often one finds subclinical seizures or electroencephalographic abnormalities in the relatives of patients with idiopathic epilepsy. The seizures do not appear to be due to a scar on the cortex, but rather to a disturbance of upper brain-stem structures which have not been identified pathologically. Penfield and Jasper have coined the term '"centrencephalic epilepsy" for these patients who seem to suffer from a primary disturbance of consciousness as part of the seizure. These patients form the bulk of the group with idiopathic epilepsy. Grand mal seizures are the most common type. Some patients, especially young children, have petit mal staring spells, often with blinking of the eyes and chewing movements. These children may also have generalized grand mal seizures without aura. Rarer forms of seizures in these patients are akinetic drop attacks and myoclonic jerks.

The Treatment of Seizures

It is often difficult to decide if a seizure is symptomatic or idiopathic when the patient first consults you. All patients, therefore, are entitled to a careful evaluation. A good history, especially a clear description of the seizure, is of the utmost importance in evaluating the patient. A complete physical and neurological examination must be performed; and one should also check for the possibility of hypoglycemia, hypocalcemia, drug intoxication or withdrawal and syphilis. Most patients should receive an x-ray of the skull and a lumbar puncture. The electroencephalogram is also an exceedingly useful test, more helpful in determining the type and cause of seizure than in making the diagnosis as such. A certain number of patients, especially those with pure grand mal seizures, will have a normal electroencephalogram despite the best efforts of the examiner. Also, gross electroencephalographic abnormalities may be present in the absence of clinical seizures, especially in the relatives of centrencephalic epileptics. Contrast studies such as angiography and pneumoencephalography should be reserved, as a rule, for those patients with focal neurological signs.

Emotional Support

Before the doctor reaches for the prescription pad, the patient should be given a thorough explanation of his disease and a good deal of emotional support. It is often necessary to repeat this in a second visit and to allow the relatives to air their anxiety and obtain reassurance.

Precautionary Measures

It is wise to forbid driving (and airplane piloting!) until the seizures are under perfect control. Water sports are usually safe if seizures are infrequent and if the patient is closely accompanied by an expert swimmer. General measures such as adequate rest, a good diet, and counsel for and treatment of severe emotional upsets are very important. The adherence to a regular nonstressful regimen often spells the difference between complete and partial control of seizures. Diuretics for five days preceding menstruation are helpful in women whose seizures occur at that time. The patient should be encouraged to lead as normal a life as possible. More epileptics are handicapped by overly protective and anxious relatives than by uncontrolled seizures.

Anticonvulsants

Table 1 lists a few common anticonvulsants in order of decreasing safety; no attempt at an exhaustive list is attempted. Most patients can be handled with these four drugs either alone or in combination. When discontinuing any anticonvulsant, reduce the dose slowly over several weeks to avoid status epilepticus, which often occurs if drugs are suddenly withdrawn. As a rule, do not consider the withdrawal of anticonvulsants until the patient has been seizure-free for at least two years, and even then do so slowly over six to twelve months. Periodic blood counts should be performed. The more difficult problems should be referred to a neurologist.

Surgery

Surgery is indicated in those epileptics with (1) tumors or (2) severe seizures arising from a limited area of injury which have not been controlled after special handling with drugs. A very small percentage of patients meet these criteria.

ANSWER TO WHAT'S YOUR DIAGNOSIS

(from page 1430)

The shadow (X-ray Figure 1) produced in the intravenous cholangiogram had the positioning of the gallbladder. A needle was inserted through the ribs and a purulent material encountered. Subsequent exploration into the peritoneal cavity relocated the abscess within the substance of the liver, having the length, breadth and approximate position of the x-ray shadow. It is speculated that the dye, when given intravenously, entered the abscess cavity, but when injected through the T-tube there was no communication (Figure 2).

The patient has made a complete and satisfactory recovery without recurrence of symptoms. Intravenous cholangiogram subsequently revealed no gallbladder shadow and the ring-like calcification was interpreted as being calcification of a vessel.

There are parentheses in worry. — Balzac

Papillary Muscle Dysfunction

As EARLY as 1803 congestive heart failure and death resulting from rupture of a papillary muscle was known to occur, the mechanism of death being pulmonary edema secondary to acute severe mitral insufficiency.[1] By 1950 thirty-seven cases had been reported[2] and by 1963 this total had reached sixty-six.[3] No clear account could be found of mitral insufficiency and congestive heart failure as a result of dysfunction of a papillary muscle without rupture until Burch and associates described two cases in 1963.[4] In both cases the onset of the murmur was acute and followed myocardial infarction. Both cases ended in rapid death due to congestive heart failure, and both cases had the sudden onset of a murmur typical of mitral insufficiency as a clue to the diagnosis. Subsequently the same authors collected eleven additional cases and described clinical and electrocardiographic characteristics.[5,6]

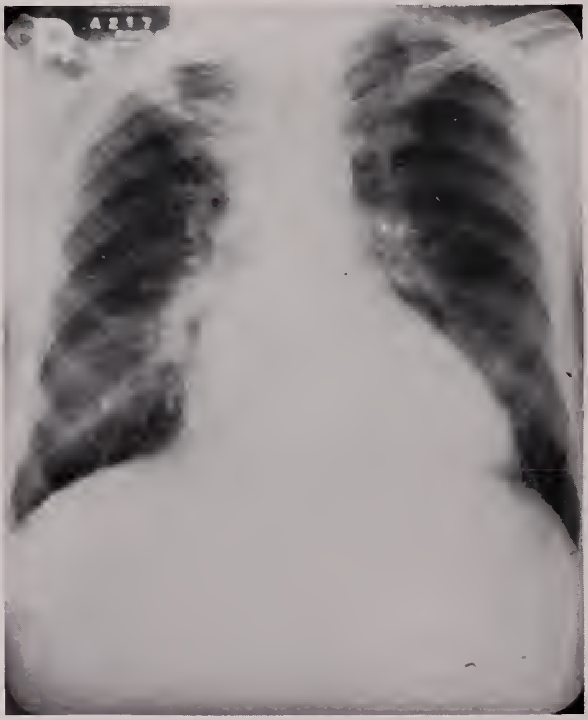

Fig. 1 — P-A chest roentgenogram demonstrating cardiomegaly and pulmonary venous congestion.

The frequency of papillary muscle infarction without rupture producing mitral regurgitation is emphasized by a subsequent report of fifteen additional cases.[7]

Because of the availability of corrective surgery for mitral valve deformities awareness of this entity is important.

The following case history deals with a patient without a history suggesting myocardial infarction. The patient was, in fact, undergoing evaluation for cardiac surgery because of severe mitral insufficiency thought to be of rheumatic origin at the time of his death.

Case Report

The patient was a 53-year-old white male at the time of his final Ancker Hospital admission in January, 1964. A review of his record revealed

An Unrecognized Cause of Mitral Insufficiency

JOHN M. BURNS, M.D.*
THOMAS E. LAYMAN, M.D.
St. Paul, Minnesota

periodic clinic visits and hospitalizations from 1934 to 1953 for sundry complaints. In 1953 he was seen in the orthopedic clinic for hip pain. An x-ray examination of both hips was normal. Over the next eight years he was essentially asymptomatic. In 1961 he was hospitalized for cellulitis of the face as well as for alcoholism. Cardiac findings were considered normal at that time.

In June, 1962, he was hospitalized with his first episode of congestive heart failure. There was no history of angina or chest pain. An electrocardiogram showed delay of intraventricular conduction but no evidence of myocardial infarct. An apical systolic murmur which radiated to the left axilla was present. He was treated with digitalis and diuretics and discharged with the diagnosis of congestive heart failure due to rheumatic heart disease with mitral insufficiency.

Over the next 17 months he had seven admissions for congestive heart failure, each bout becoming

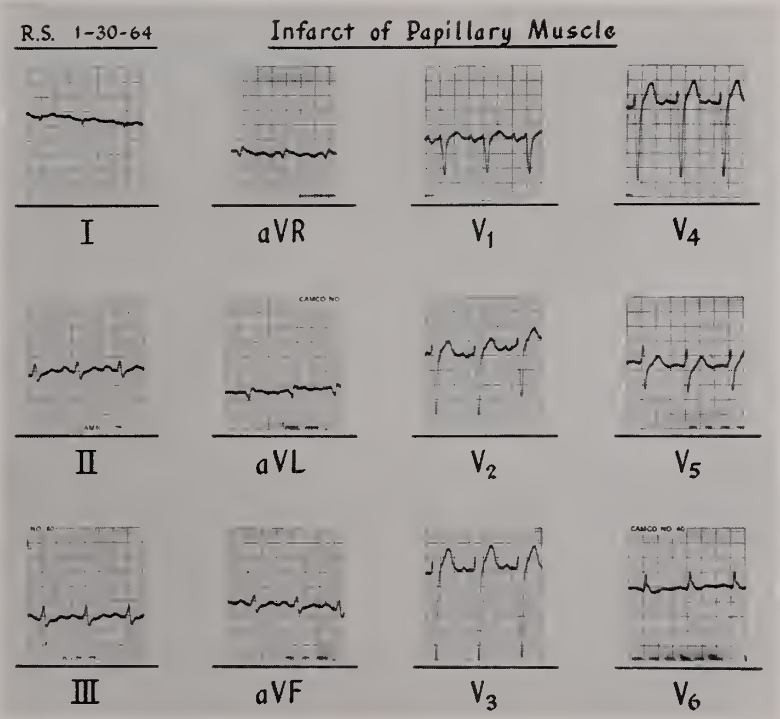

Fig. 2 — Electrocardiogram. A delay in intraventricular conduction is present. None of the described features of papillary muscle infarction are present.[6]

more severe. At no time could a history suggestive of myocardial infarction or angina pectoris be obtained. The murmur remained unchanged.

At the time of his last admission in January, 1964, his cardiac status was class IV. The chest roentgenogram at that time demonstrated marked cardiomegaly with dilatation of the left ventricle and congestive changes in the lungs (Figure 1). The electrocardiogram (Figure 2) revealed right axis deviation and ST-T wave changes of digitalis effect. The Q wave in AVL was thought to be due to the axis shift and electrical rotation of the heart. At that admission, mitral valve replacement was considered as definitive treatment for the mitral insufficiency. In preparation for surgery a left heart catheterization was performed. There was no demonstrable systolic gradient across the aortic valve. Most striking was an initial ventricular diastolic pressure of 20 mm. of mercury, and an end diastolic pressure of 37 mm. of mercury indicating a severe degree of left ventricular failure. Angiography was performed and demonstrated a large dilated left ventricle with severe regurgitation (4+) into the left atrium. This was best demonstrated in the lateral view (Figure 3). Aortography demonstrated no aortic insufficiency; the coronary arteries did not fill adequately for evaluation.

Intensive medical management of the left ventricular failure was instituted. On the third day following catheterization the patient suddenly developed shock and pulmonary edema. He denied pain. Ventricular tachycardia was noted on the electrocardiogram. In spite of vigorous therapy this arrhythmia progressed to ventricular fibrillation and the patient expired.

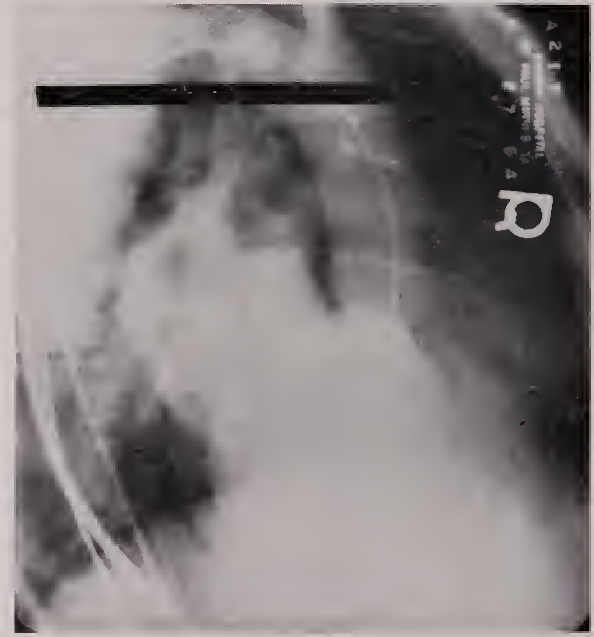

Fig. 3 — Left ventriculogram demonstrating the presence of contrast material in both the left ventricle and left atrium.

Autopsy Findings

At autopsy the heart weighed 755 grams. A very dilated and flabby left ventricle was noted. The coronary arteries showed grade 2 and focal grade 3 atherosclerotic changes. Right and left ventricular hypertrophy was present. The cut myocardium demonstrated a large area of subendocardial fibrosis in the anterior wall of the left ventricle. This extended laterally and inferiorly and involved both papillary muscles. These were noted to be very pale, thin, and atrophic (Figure 4). The cardiac valves and the chordae tendinae were normal.

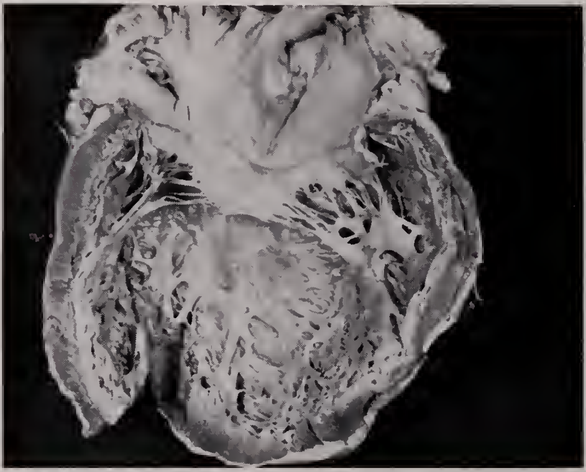

Fig. 4 — Gross pathologic specimen of the opened left ventricle. The papillary muscles are thinned and atrophic. There is no rupture.

Microscopic sections of the infarcted papillary muscles demonstrated a marked degree of fibrosis and disruption of the normal architecture (Figure 5). This was even more striking when compared with a section of normal papillary muscle which supplied the tricuspid valve (Figure 6). Collagen staining of the section of the infarcted muscle was also striking, the collagen making up a large part of the total muscle.

Discussion

For a clear understanding of how malfunction of the papillary muscles can allow severe mitral regurgitation, a brief resume of the normal function of the mitral valve apparatus including the papillary muscles is required.

Normal Function of the Papillary Muscles

In the left ventricle two papillary muscles are found. From each muscle head arise several chordae tendinae which insert into both leaflets of the mitral valve. Studies by Rushmer[8] have shown that the papillary muscles normally hold the valve leaflets within the ventricular chamber under tension. The free edges of the leaflets never pass higher than the atrioventricular ring. Following atrial systole the leaflets move together in light apposition, "floating" up under the influence of eddy currents produced by continued ventricular filling.[9] Normally, ventricular systole begins immediately thereafter, being initiated in the subendocardial area of the papillary muscles. Thus, they are the first area of the myocardium to contract. Their contraction causes the leaflets to be pulled firmly downward and together into a firmer degree of apposition. The myocardium now contracts in the phase of "isovolemic contraction," during which time the intraventricular pressure rises rapidly. This increase in pressure tends to balloon the mitral leaflets toward the atrium, but because of the firm anchor of the contracted papillary muscles, only the diaphragm of the leaflets moves upward, the free edges being held within the ventricular cavity. This ballooning effect causes a tight closure of the mitral valve.

Immediately following the isovolemic contraction phase is the phase of ventricular ejection. During this period pressures rise to the normal systolic level. This presents very high pressure per unit area to the leaflets, and certainly without the anchoring effect of the papillary muscles, the leaflets would evert into the atrium, allowing a severe degree of regurgitation.

Papillary Muscle Dysfunction

When papillary muscle dysfunction exists, the anchoring effect of their contraction is not present. However, with isovolemic contraction the intact chordae are able to prevent incompetency, and during production of the first heart sound the mitral valve is competent. During the phase of ventricular ejection the intraventricular pressure rises to the normal systolic level. Without papillary muscle contraction anchoring the mitral valve leaflets, insufficiency occurs and a murmur is produced. This murmur differs from the "pansystolic" regurgitant murmur usually associated with rheumatic mitral valve insufficiency in that there is a delay in onset

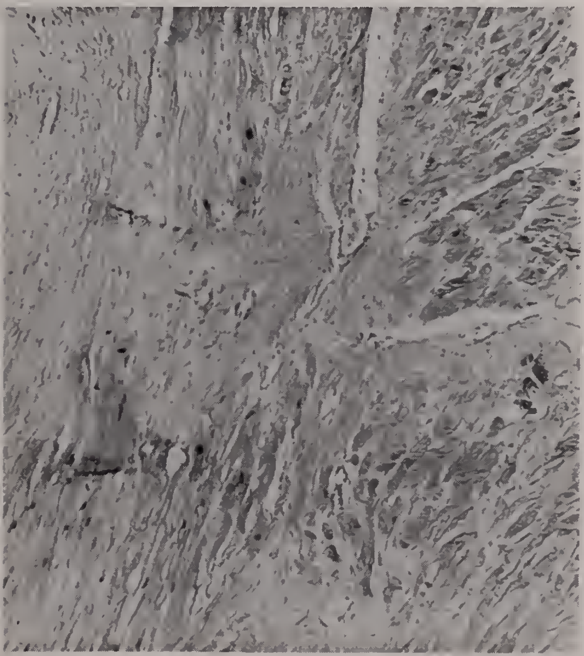

Fig. 5 — Microscopic section of the infarcted papillary muscle. Fibrous connective tissue predominates.

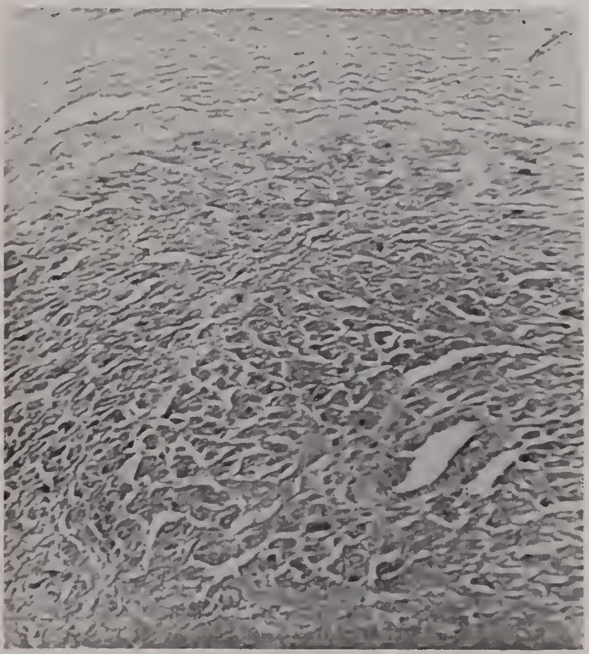

Fig. 6 — Microscopic section from right ventricular papillary muscle, demonstrating normal architecture.

from the first heart sound. The feature of delayed onset of this murmur, which is commonly of an "ejection" crescendo-decrescendo quality, is most important and serves to differentiate it from the murmurs of either rheumatic mitral insufficiency or rupture of papillary muscle wherein the murmurs are pansystolic.[4]

A more common example of dysfunction of the papillary muscles is seen in the case of premature ventricular beats. In such a case a ventricular systole is initiated before the leaflets have closed. Because the focus is ectopic, the papillary muscles are not the first areas to contract, and their effectiveness in closing the leaflets is lost. Thus, moderate degrees of insufficiency may occur.

In the case presented, dysfunction occurred as a result of loss of myocardial tissue in both papillary muscles. Because tissue was lost the atrophic muscles could no longer effectively hold the leaflets within the ventricular cavity; they could not contract effectively to initiate a firm apposition of the leaflets; and finally, as the ventricle contracted and as pressures rose, they could not act as anchors of the free edges of the leaflets, but allowed them to separate. Severe regurgitation through the mitral valve was the end result.

The adage that "Mitral insufficiency begets insufficiency" holds true in this case and undoubtedly later played a part in this patient, as the ventricle and the atrioventricular ring dilated. An already regurgitant valve became more regurgitant, and the cycle repeated itself. Death was the result.

Summary

A case is reported in which mitral insufficiency caused severe congestive heart failure. Due to lack of history suggesting coronary heart disease, a diagnosis of rheumatic valvular disease was made. Left heart catheterization demonstrated severe mitral insufficiency, a large dilated left ventricle, and pressures compatible with severe left ventricular failure. The patient expired and at autopsy was found to have coronary atherosclerosis and an old myocardial infarction with involvement of both papillary muscles. There was no papillary muscle rupture.

The function of the normal and diseased papillary muscles is discussed. Awareness of the entity of papillary muscle dysfunction due to infarction is important. Since corrective surgery for mitral valve abnormalities is increasing, the operative prognosis will depend not only on the nature of the deformity but also its cause.

Character is much easier kept than recovered. — Thomas Paine

Bell's Palsy

JEROME A. HILGER, M.D.
St. Paul, Minnesota

FACIAL PARALYSIS of sudden onset without demonstrable traumatic, neurogenic or otitic origin is termed "Bell's palsy." It has the potential for tragic and permanent disability. It has been mistakenly assumed for years that 80% of cases recovery spontaneously. This has encouraged the futile use of mild therapeutic exercises such as direct muscle stimulation in the thought that something harmless was being done to engage the patient through a period in which nothing useful could be done. This "head in sand" philosophy is untenable and bears discussion and rejection.

Eighty per cent of cases do not recover spontaneously if any discrimination is used in determining "recovery." Partial function and the bizarre character of facial synkinesis or "associated movement" are unacceptable levels of "recovery." Indeed, when discriminating standards are applied only 55% of Bell's palsy victims have satisfactory return of function. For the rest, permanent disability varies between troublesome and tragic as shown in Mathew's[1] series of 156 patients in whom results were graded as follows: (a) complete recovery; (b) incomplete grade 1 (incomplete recovery with no disability); (c) incomplete grade 2 (incomplete recovery with slight disability); (d) grade 3 (poor result). Mathews related the degree of recovery to the time of appearance of first movement (Table 1).

TABLE 1*
Degree of Recovery

Movement Observed	Complete Recovery	Grade 1	Grade 2	Grade 3	Total
4 weeks	74	6	18	4	102
4 to 8 weeks	0	1	10	7	18
8 to 12 weeks	0	0	4	7	11
12 or more weeks	0	0	1	13	14
Total	74	7	33	31	145

*From Mathews[1]

Diagnosis

All cases of facial paralysis see a physician as a matter of emergency once the enormity of the disability is apparent. Even those without associated pain see the disability as an acute disaster. Here is a time when medical piddling and procrastinating is costly, for adequate medical management can be valuable if immediately applied.

Careful otologic evaluation and neurologic study exposes specific disease in a few instances[2,3] of acute facial paralysis. Both are vital parts of the primary examination before the case can be categorized as an idiopathic or Bell's palsy. Pain in and about the ear of the involved side indicates a grave outlook for the Bell's palsy victim, but, where pain is a feature of onset, care must be used in examining for an herpetic eruption in the canal and conchal skin, else a geniculate herpes may be misdiagnosed as Bell's. In this regard, Cawthorne[4] has discussed the very real value of routinely performing the lacrimation test. This is simply performed by draping a filter paper strip from each lower conjunctival sulcus. The patient then is given ammonia to sniff. Equal lacrimation denotes pathology below the geniculate level as in Bell's palsy. The potential for erroneous diagnosis through incomplete study has been stressed by Walsh.[5]

In addition to excluding otitic or neurologic cause the first examination must establish the severity of nerve involvement through electrical testing.

Physiology

Under resting condition the membrane of a single nerve fiber is 20 to 100 times as permeable to potassium as it is to sodium. The membrane has a positive charge on the outer surface and a negative charge on its inner surface. However, this differential drops to zero or even reverses itself when the membrane becomes excited. This excitation may be physiologic or may occur by mechanical injury, or electrical stimulation, etc. This reversal of charge lasts but a half millisecond in larger nerve fibers before it returns to normal resting potential. This sequence of potential change is termed the "action potential." It causes an electrochemical impulse to be transmitted along the nerve fiber. The central core of the myelinated nerve fiber is the axon, and the surface of the axon is believed to be the actual conductive membrane. The axon is filled in its center with axoplasm — a viscid intracellular fluid. Surrounding the axon is a myelin sheath. Myelin is an excellent insulator and prevents almost all flow of ions through its substance. Approximately at each millimeter along the length of the axon, in a myelinated nerve fiber, the myelin sheath is interrupted at a "node of Ranvier." Because of the absence of myelin at this point ions can flow freely — indeed, the membrane here has been shown to be up to 500 times more permeable than the membrane of some unmyelinated nerve fibers. For this reason the electrical impulse generated by the action potential is conducted from node to node rather than continuously along the entire fiber. This process is called "saltatory conduction," and probably provides increased speed of nerve conduction and decreased metabolic requirement for the ion transfer process.

Larger nerve fibers generate greater numbers of electrical charges at each successive point along the membrane; therefore, the velocity of nerve conduction is almost directly proportional to the diameter of the nerve fiber.

A nerve trunk is made up of many fibers. The intensity of the impulse in a nerve trunk is controlled by spatial summation and temporal summation. Spatial summation refers to the number of individual fibers firing in a given nerve trunk. The action potentials of these fibers will summate at many motor end plates to activate many muscle units. Temporal summation relates to the number of impulses traveling along a single nerve fiber each second. This may, for example, be a hundred impulses per second. Muscle cannot react and recover this rapidly. Therefore, the impulses cumulate at the motor end plates during the muscle refractive period. This cumulation of impulses provides a greatly enhanced next stimulus. Normally nerve signals of different intensity vary in both spatial and temporal summation. In other words, the stronger the signal the greater the number of fibers involved and the greater the rate of impulse transmission by each fiber.

Experimental Nerve Destruction and Regeneration

When a peripheral nerve fiber is cut, the fiber distal to the cut will conduct impulses caused by electrical stimulation for two to three days. After that the entire nerve fiber peripheral to the section becomes inactive and the axons begin to degenerate. This is commonly termed "Wallerian degeneration." The neuronal body in the spinal cord undergoes changes termed, collectively, chromatolysis.*

Regeneration at the central stump of a single severed fiber is characterized by the elaboration of 10 to 100 searching fibers seeking any sheath in the peripheral end of the cut nerve. Once any sheath is found the searching fiber will follow it in peripheral growth at an average rate of a millimeter a day. Meanwhile the sheath cells enwrap the fiber and a new layer of insulating myelin is formed.[6] When many divided fibers are present the proximal searchers have no method of adopting the proper sheath and peripheral motor confusion is the end result (synkenesis or "associated movement").

Pathology

The presumed pathology in Bell's palsy[7,8] is acute, functional ischemia followed by capillary (endothelial) injury, transudation and constricting edema within the close confines of the tough nerve sheath inside the long bone canal (the greatest nerve length so confined in the entire body). The process of ischemia and secondary edematous constriction can result in: (1) neuropraxia (functional loss of conduction with axis cylinders anatomically intact) or (2) axonotmesis (loss of conduction due to necrosis of the axis cylinders); (3) a combination of both pathologies; or, (4) progression from neuropraxia to axonotmesis. By means of the nerve excitability test one can be differentiated from the other. This method of evaluating the status of the disordered nerve is cited by Richardson as superior to other modes.[9] He pointed out that nerve impulse velocity measurements were not readily applicable in facial palsy because the stimulus could not be applied proximal to the pathology. Application of stimulus peripheral to the pathology gave tardy and incomplete information with nerve impulse velocity measurements.

Similarly, Richardson cited evidence that strength-duration (I/T) curves depicting the threshold intensities of stimuli of various durations required to produce visible muscle contractions when applied over the area of motor nerve penetration of a muscle had no advantage over the simple nerve excitability test.

Electromyographic methods were noted to produce interesting information relative to degeneration and regeneration activities, but the information of greatest importance in the first days of the Bell's pathology lagged well behind that provided by the simple nerve excitability test.

Nerve Excitability Test

The nerve excitability test is simple and direct when performed with a proper instrument[10] applied at the zone of crossing of the main facial nerve trunk over the edge of the vertical mandibular ramus. The stimulator, used by the author, furnishes a square wave of negative polarity and duration of 600 microseconds with a repetition of 6 cycles per second. It automatically compensates for variations in the resistance of the circuit (and, therefore, in tissue resistance, i.e. anatomic variations) and thus delivers a current of determinable strength. The strength of current necessary to evoke response in a given individual is comparable from one side to the other. The acute palsy victim may show one of three findings: (1) identical muscular response to the same strength stimulus applied to the normal and the palsied nerves; (2) decreased (but present) response on the troubled side requiring greater stimulus (current); (3) absent response on the involved side. The prognostic as well as the diagnostic value of adequate nerve excitability test is shown in the relation between test response and eventual recovery (Table 2).

The fact that serial (daily) nerve testing is valuable in following initially unimpaired nerve excitability cases is demonstrated by Campbell[11] and by Laumans[12] and well illustrated in Table 3.

TABLE 2*
Nerve Excitability

Nerve Excitability	Cases	Full Recovery	Incomplete Recovery	
			Grade 2	Grade 3
Unimpaired	61	55 (90%)	4 (7%)	2 (3%)
Diminished	21	10 (48%)	9 (43%)	2 (9%)
Absent	35	7 (20%)	11 (31%)	17 (49%)

Medical Management

Intelligent medical management of Bell's palsy is emergent. It should be started immediately upon recognition of the problem. Functional vascular alteration has been the focal objective of most recommended treatment. Vasodilation by physical therapeutic or pharmacologic methods has had proponents. Neural blocking therapy with intravenous procaine or cervical sympathetic block has favor with others. Endothelial repair with steroids has been recommended as has histamine-binding with heparin.

The authors feel that inpatient management with intravenous procaine-nicotinic acid infusion is a basis for good management. Its effectiveness is attested by the occasional neuropraxic case that has restoration of motor function during the infusion period. This invariably relapses to paresis within an hour or two of infusion termination, but the prognosis in such a case is invariably good and the evidence of restorative vascular effect is undeniable. The method of therapy as used follows:

A solution of 0.2% procaine hydrochloride is prepared in 5% dextrose (1 gm. of procaine hydrochloride in 500 cc. of 5% dextrose solution). To this solution is added ascorbic acid 1 gram and nicotinic acid 100 milligrams.

The rate of infusion is adjusted to produce a satisfactory reaction for both the nicotinic acid (warm flush) and the procaine (slight numbness, thick tongue, mild floating sensation). Extremes of these reactions should be avoided. Excess in one or the other should be balanced by increase or decrease in the nicotinic acid quantity in subsequent solutions.

A 250 cc. quantity of the above is given in one infusion period. It is repeated three or four times per day. No residual half-bottle is kept for longer than twelve hours.

The nurse (and the patient) are instructed to observe for facial movement during the latter part of each infusion period. This intravenous sequence is followed for seven days or until the nerve excitability test findings are stable for a seven day period.

In addition to the intravenous infusion 100 milligrams of hydrocortisone or its steroid equivalent are given orally in divided doses, each day, for a week or until the nerve excitability test findings are stable for that period of time.

The patient is instructed in uplifting facial massage and follows a ten-minute routine four to six times a day. He is also instructed in the care of the exposed cornea. Manual lid movement to moisten the cornea is practiced habitually through the day. The lid is manually closed at night and may be secured with a strip of transparent tape. The lower lid sag can be supported by an elevating strip of transparent tape lateral to the lateral canthus during the day. Protective eye glasses are advisable, particularly outdoors in the wind.

Surgical Management

It is of paramount importance that the patient with normal or decreased nerve conductivity be tested daily during the medical treatment period. Progressive decrease in responsiveness, even a week or more after onset, indicates a poor prognosis (Table 3). Therefore, progressive daily decrease in nerve conductivity is a clear-cut indication that surgical decompression of the nerve trunk be performed forthwith as an emergency effort to halt axis cylinder disruption. The loss of axis cylinders distal to the pathology, once established, makes full recovery impossible. A nerve trunk containing thousands of axis cylinders cannot recanalize this vast number of peripheral tubules accurately and completely. Partial permanent loss of muscular tone and strength can be less disastrous than the permanent "discord" of emotional expression from disorganized regeneration of the peripheral axons. Campbell's[11] figures show that of cases progressing to total degeneration subsequent to first examination only 20% made a satisfactory recovery.

For the nerve in which neuropraxic elements with axis continuity are present in useful numbers the spontaneous and medical resolution of vascular pathology should find those elements improving in nerve test response within weeks. Where no nerve excitability is present after two weeks it can be assumed that the pathologic state within the facial canal is of an unremitting and severe type.

For the patient exhibiting absent electrical response at first nerve excitability test, the prognosis for full recovery is poor. The axis cylinders are already disrupted. The long, fumbling, and disorderly recanalization of the thousands of distal sheaths by the groping, amoeba-like proximal stumps must go forward until the motor end plates are reached.

Laumans[13] has demonstrated that where complete degeneration has occurred full recovery is out of the question. Jongkees[14] points to the fact that such patients constitute a select and tragic classification and have a uniformly poor outlook for good recovery — a sharp contrast to the cheery expectancy of the neuropraxic case. It is Jongkee's feeling that decompression surgery should be performed immediately since in this selected group further conservative management has proven almost 100% unsatisfactory.

There is sound evidence from many sources that resolution of the pathology can be expedited with skilled microsurgical decompression of the nerve from the middle ear to the stylomastoid exit. This is urged when nerve excitability is absent after two weeks of observation and adequate medical management. Long delay can result in partial or total replacement of the disintegrated fibers by fibrous tissue.[15-17]

Summary

1. Bell's palsy is an acute medical emergency.

2. Careful otologic and neurologic study is necessary since the diagnosis is made by exclusion of other cause for the acute palsy.

3. Immediate (first day) evaluation of the state of the nerve by the relatively simple nerve excitability test must be followed by daily retest to follow the progression of the pathology.

4. Aggressive inpatient medical management is outlined.

5. When severe pathology persists or progresses in spite of treatment a tragic prognosis can be improved through surgical decompression of the nerve.

The distance is nothing; it is only the first step that costs. — Mme. Du Deffand

Man is a piece of the universe made alive. — Emerson

PEUTZ-JEGHERS SYNDROME

This syndrome is characterized by polyposis of the mucosa of the small intestine and unusual skin and mucosa pigmentation. The disorder is familial in fifty per cent of the cases inherited as a simple mendelian dominant. It occurs in all age groups and in both sexes.

The clinical manifestations consist of colicky abdominal pains, gastro-intestinal bleeding and, in some instances, episodes of invagination with intestinal obstruction, especially in children.

The areas of cutaneous pigmentation consist of dark brown melanin deposits, appearing at one to five millimeter round, oval or stippled areas on the lips, the skin of the face and digits, the nasal area, around the eyes and mouth and occasionally on the genital or rectal mucosa.

The polyps are demonstrated roentgenologically, most commonly located in the small intestine, but can also be found in the stomach, large intestine, and rectum. Low-grade malignant degeneration has been found to occur in twenty per cent of reported cases.

Resection of the involved area of intestine is indicated as a prophylactic measure, and becomes imperative when severe bleeding or obstruction develop.

The Papyrus Ebers

Those about to study Medicine, and the younger Physicians, should light their torches at the fires of the Ancients. — Rokitansky

The Ebers Papyrus is an excellently preserved Egyptian scroll 12 inches wide and 68 feet long, written in 1500 B.C. It consolidates into a unitary document the record of Egypt's medical remedies from 3400 B.C. up to the time of its transcription from the original hieroglyphic form into more legible hieratics.* The papyrus comprises Book 40 in the totality of 110 Egyptian books known as the Hermetic Books, purportedly containing the sum of all human knowledge, and is one of six dealing with ancient medicine — antedating even the Greek contributions to medical science.

The Egyptologist so fortunate as to secure the papyrus from a native Egyptian was Georg Ebers (1837-1898), who took his precious find to the University of Leipzig where it now reposes. The abstruse, archaic, and somewhat controversial document was ably translated into German by D. H. Joachim, who said: "It surpasses in importance all other medical papyri in the richness of its contents and its completeness and perfection. It is the largest, most beautifully written, and the best preserved of all the medical papyri."** Joachim's German version was later translated into English by Cyril Bryan, whose work is highly commendable not only for its exposition of the text, but also for the warm, human insight it injects. The medical section of the Hermetic Books consists of Book 37 on Anatomy, Book 38 on Diseases, Book 39 on Surgery, Book 40 on Remedies, Book 41 on Diseases of the Eye, and Book 42 on Diseases of Women. Subsequent issues of MINNESOTA MEDICINE will explore the Ebers Papyrus in more detail.

Intragastric photography studies[1]

A/ E. B., male, age 48. Normal antral contraction. Pyloric opening is not seen. It is difficult to differentiate a deep prepyloric contraction from a "pyloric fleurette" or true pylorus.

B/ Same subject after 6 mg. of propantheline bromide intravenously; antral contractions ceased. The pyloric orifice remained open and was easily identified. Better visualization of the antrum was also obtained.

Now you can see Pro-Banthīne® at work

(propantheline bromide)

Pro-Banthīne is so effective in anticholinergic action that it may be employed in visualizing the entire pyloric region.

In addition to the intragastric photographs, cinegastroscopic studies[2] have demonstrated graphically not only its effectiveness but the superiority of Pro-Banthīne over belladonna alkaloids.

Pro-Banthīne produced complete cessation of gastric, antral and pyloric motor activity with a dose of 6 mg. intravenously. This is approximately one-third the usual oral dose of 15 mg.

Atropine at full normal dosages did not produce such cessation. It required double the usual oral dose of atropine, 0.8 mg. intravenously, to duplicate the aperistaltic action of Pro-Banthīne. This dose of atropine produced pronounced discomfort and tachycardia with ventricular rates as high as 150 per minute.

It is this pharmacologic superiority of Pro-Banthīne which has made it the most widely prescribed anticholinergic in such conditions as peptic ulcer, functional hypermotility, irritable colon, pylorospasm and biliary dyskinesia.

Dosage—The maximal tolerated dosage is usually the most effective. For most *adult* patients this will be four to six 15 mg. tablets daily in divided doses. In severe conditions as many as two tablets four to six times daily. Pro-Banthīne (brand of propantheline bromide) is supplied as tablets of 15 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type ampuls of 30 mg.

Side Effects and Contraindications—Urinary hesitancy, xerostomia, mydriasis and, theoretically, a curare-like action may occur. The drug is contraindicated in patients with glaucoma or severe cardiac disease.

A Medical Internship under Dr. Arthur B. Ancker*

1904-1905

WITH THE NEW Ancker — City and County Hospital rising up majestically on University and Jackson Streets in St. Paul, it calls attention to the great contrast between that building with its great teaching staff and the old City and County Hospital overlooking the Mississippi River on West Seventh Street when Dr. Arthur B. Ancker was running the whole show.

The City-County Hospital and Dr. Ancker were so closely related that one can not speak about one without the other. He was the hospital! Dr. Ancker's personality penetrated the whole institution from the kitchen to the front office.

He and his staff had selected seven of us, nice green students fresh out of medical school, for that class of interns for 1904-05. They were Doctors Carl A. Larson, George Dittman, Tobias Birnberg, William F. Frost, Edward M. Mauer, A. G. Schulze and myself. We all had our M. D. degrees, for at that time it was not necessary to have an internship to get the degree or to be able to practice. This was most important to all of us as I will point out later.

The hospital worked on the rotating system just as they do today but it must be remembered that this was 1904 — sixty years ago — and even though we had the same services, we were offered nowhere near the depth of instruction that is common now. There just wasn't the medical knowledge then. Pathology was very simple by today's standards. We could count red and white blood cells, examine urine and we did smears for staph and strep. Before my year was over we started to differentiate between the mononuclears and the polynuclears. But most of the time we simply counted white cells and paid no attention to the differential count. We did a diazo urinary test and a Widal blood test for Typhoid Fever but when it came to bacteriological work, we sent our diphtheria cultures to the City Health Department at City Hall. No routine autopsies at all. If we had an autopsy, it was to look at something rare or unusual. Autopsies were simply for gross pathology, for little microscopical work was done. That was the extent of our laboratory pathology.

X-ray equipment was of the crudest form and a far cry from the most sensitive and advanced equipment that is being installed for the radiology department in the new hospital. Eight years before I arrived at the hospital the first successful X-ray picture was taken. Professor Fred S. Jones of the

Some people get away from colds and sinusitis
by getting away from frigid weather

. . . but if your patient can't get away, relieve sneezing, running nose, and congestion of colds and sinusitis all day or all night with one

ORNADE® SPANSULE® CAPSULE
Trademark brand of sustained release capsule

Each capsule contains 8 mg. of Teldrin® (brand of chlorpheniramine maleate), 50 mg. of phenylpropanolamine hydrochloride, and 2.5 mg. of isopropamide, as the iodide.

Summary of contraindications, cautions and side effects: Do not use in patients with glaucoma, prostatic hypertrophy, stenosing peptic ulcer, pyloroduodenal obstruction or bladder neck obstruction. Use with caution in the presence of hypertension, hyperthyroidism, or coronary artery disease. Drowsiness; excessive dryness of nose, throat or mouth; nervousness or insomnia may occur on rare occasions but usually are mild and transitory.

Before prescribing, see SK&F product Prescribing Information.

Smith Kline & French Laboratories SK&F

Physics department of the University of Minnesota produced the picture and Dr. Millard performed the operation: the removal of a bullet from a man's leg. The newspapers for that day reported that the doctor was "aided by the photograph (and he) cut directly to the spot where the bullet was shown in the X ray." According to the newspaper, this was the first operation with the help of X ray in the northwest.

The excellent teaching staff made up for the lack of medical knowledge and modern equipment. We had giants of medicine that made our instruction at City and County Hospital one of the outstanding teaching hospitals in the nation and certainly the best in the west.

One of the great opportunities of a lifetime was to train under Dr. A. J. Gillette, orthopedic surgeon, sometimes referred to as the 'Dr. Lorenz' of America; Dr. Justice O'hage, surgeon, who took out the first gall bladder in the United States at St. Joseph's Hospital in St. Paul — the 10th recorded cholecystectomy in the world. Doctors E. J. Abbott, J. A. Rothrock, Walter R. Ramsey and Longstreet Taylor, all come to mind as the medical giants of that day, but there were many, many more.

These men were appointed to the hospital staff in 1892, the first time Dr. Ancker had a full hospital faculty that gave their time and knowledge without compensation. Five years before the first appointed staff, records show the first intern and the only one for that year. His name was Dr. F. H. Holland and Dr. Ancker was his only teacher.

In 1896 Homeopathic doctors were invited to join the faculty staff but their invitation came under extreme opposition from Dr. Ancker, major-domo of the hospital. Dr. Ancker did not want to recognize homeopaths because of their fundamentalist faction, but he would recognize the liberal group. Again, it was the same kind of fight that went on at Hahnemann College in Chicago as late as 1920, which led to its decline and closure. Also, as he was an allopath, he had doubts about the two groups working side by side in the hospital. There was a running battle between Dr. Ancker and the more out-spoken city Homeopaths for more than two years. The newspapers were full of the controversy. The Homeopathic doctors even threated court action, but only because Dr. Ancker was so adamant and dictatorial in managing the City and County Hospital. Dr. B. H. Ogden and Dr. Henry Hutchinson were of the liberal group of Homeopaths and much more open-minded than the fundamentalists, who clung to believing absolutely in "symptom matching only." But Dr. Hutchinson in his quiet, intelligent way finally brought Dr. Ancker around to an agreement.

Even these illustrious and forth-right staff doctors knew it was Dr. Ancker's Hospital. Dr. Ancker saw to that himself; that anyone in and around the institution worked within *his* rules or they didn't. It was as simple as that. But there was a reason for this.

In 1872, ten years before Dr. Ancker set foot in Minnesota, the Ramsey County Board of Control bought from Dr. Jacob Stewart, later mayor of St. Paul, an old stone mansion and its grounds for hospital purposes. This was the same property where the present 'old' Ancker Hospital stands just off West Seventh Street. The Board got the property for a 'song,' something around $20,000, according to Dr. Ancker's records.

Dr. Ancker had received his medical degree from the Medical College of Ohio in Cincinnati and had been in St. Paul only a year when he was named by the Board to be superintendent of the City and County Hospital. The Board of Control saw in Dr. Ancker just the man they needed to start a hospital. Therein lies the devotion Dr. Ancker had for his hospital: he got it started; he worried with it and he alone was responsible for its growth.

The 'hospital' consisted of ten rooms with two bathrooms and a barn out in back. Dr. Ancker's contribution to the institution was a few miscellaneous instruments and a prescription pad, all of which he could carry in his pockets. He said at the time, he "was the whole institution." He had no staff, no nurses, no training school, nothing. The interior equipment included 27 stoves and a collection of kerosene lamps; no electricity,

gas or sewage disposal and they carried their water in with buckets from a well on the property. In the beginning, he had one woman working for him who scrubbed the floors and cooked the food. The barn out back was used, not only for Dr. Ancker's horse but also, the first floor was the morgue or better known as the 'dead house.' Upstairs, the old hay loft was used for isolating contagious patients. It may have been no consolation for a delirious patient, racked with fever, to be in with the dead and one live horse, but Dr. Ancker literally had no other place for them.

Dr. Ancker saw all the patients personally and if all the beds were full, his rounds would include forty people. If he ran into difficulty, he sometimes would send for either Dr. Charles A. Wheaton, Dr. Everett G. Abbott or Dr. Edward C. Spencer, then well-known practicing physicians in St. Paul. But most of the time he did everything himself. Dr. Ancker recalls that in the early days he did all the police surgery. St. Paul was still a rough and ready river town in the 1880's and early documents show he was busy with casualties from that element.

He had no operating room as we know it; he would just throw a screen across the end of one of the larger rooms and go to work behind that. It has been said that the stronger patients would be called in at night to hold the kerosene lamps over the field of operation.

Dr. Ancker was a czar who flew often and regularly into violent rages. As our class of interns would say, "Dr. Ancker is having a hemorrhage of green paint," when he went into one of his outbursts. Many times I have heard him yell, "I'll be in charge here, not the staff!"

During the time when I was under his direct rule, he was around fifty years of age, an alert, wiry, restless man. He was of light build with small hands and his features were plump. He had had his left shoulder joint incised for tuberculosis, so he had a little difficulty getting his overcoat on and he always walked with that arm hooked to his side, but otherwise it didn't seem to bother him or inconvenience him in any way.

His demeanor was such as to not tolerate any insubordination. He would storm into a room and reach way up under a bed and if finding the least amount of dust, would scream, "this place is filthy — this place isn't fit for cattle." Then he would look around and the first nurse he saw caught it. When anything occurred not to his liking, he went into his rages. It didn't make any difference who was responsible, the first person he saw — it might be a nurse at the end of the hall, or a steam-fitter fixing a pipe — the first one caught "the hemorrhage of green paint."

Dr. Ancker was everywhere at once, it seemed, for he would show up in the most unexpected places, at the least expected time. And woe be the man who was in the room if anything went wrong. He always called the interns, 'Mr.,' not 'Doctor' and I have heard him yell "Mr. So and So, I will have you to understand these are human beings that you are taking care of."

No doubt about it, Dr. Ancker ran an extremely efficient hospital. Everyone lived in terror of his temper explosions, but everything was in perfect order, from the cleanest of floors to every medical report written up and signed. If an intern did get behind in writing up his surgical notes, again the storm would descend around his head with, "do you want this hospital to go broke with law-suits, etc., etc."

Except for his explosive temperament, he was a very fine man. He had keen sense of values, high ideals, a good education and his decisions, which he enforced with his iron will, were sound. Even though his enforcement was with unnecessary severity, he saw to it that 'his hospital' was the best and above standard.

In regard to my personal experience with him I had no real trouble. I was called into his office only once and for some reason he didn't "hemorrhage his green paint" on me. He treated me like a thoughtless schoolboy and he was playing the part of a chastising father.

There was one explosive event where I was involved, but only on the fringe of the trouble. This happened near the end of my

Wallace Laboratories, Cranbury,

internship, in fact two weeks before my service was to be completed. On May 18th, 1905, The St. Paul Dispatch ran big headlines on the front page that read, "Striking Physicians at City Hospital — Interns are Discharged." Here is the story of that blaring statement and certainly more of the truth than the headlines conveyed.

Dr. William F. Frost, one of the interns in my class, didn't report directly to Dr. Ancker about the negligence of a nurse. On his own, Dr. Frost just took care of the misconduct of the nurse and then forgot about the incident. About two months later, Dr. Ancker found out about it and hit the roof. He said the incident had been reported outside the hospital without his knowledge and besides the misconduct of the nurse should have been reported to the superintendent of nurses *and* to him for proper discipline. The matter was so trivial and inconsequential that some of our members didn't even know anything about it, let alone Dr. Ancker. But he was boss and because he would not tolerate any looseness in control, Dr. Ancker fired Dr. Frost.

Dr. Frost's position was that the incident was two months old; he had not talked about it outside of the hospital and no serious damage had been done. He didn't think it necessary to take such a small thing to Dr. Ancker. He informed Dr. Ancker that he would not resign, for he was not guilty of any offense, either to the hospital or Dr. Ancker. He felt his suspension so unjust that he took his case to the Ramsey County Board of Control, over the head of Dr. Ancker.

Before Dr. Frost gave the Board his side of the question, the Board informed him no charge had been made against him and he could speak freely. Dr. Ancker was in attendance at this meeting. At the end of the hearing, he was told again no charge had been placed against him and he was to continue his work until the matter was settled, which meant that the Board would take it all up at a later meeting.

The following morning in the midst of an operation, Dr. Ancker demanded that Dr. Frost leave the operating room at once. Again, Dr. Ancker's temper showed up at the unexpected time. Also, this was the second time Dr. Ancker had suspended him without charge. When the rest of us heard about it, we all felt it was unjust and uncalled for discipline and that Dr. Ancker had gone too far. The other interns thought the only thing to do was to walk out. It was a nasty mess and when the newspapers got hold of the story they really played it up. It wasn't really a strike, for no one really intended to walk out, just go as a body to Dr. Ancker and issue a formal protest. We were only standing up for Dr. Frost.

My part in the matter was never clearly understood and this is probably my first chance to explain it all. When I went into City and County Hospital, I was the underdog, because I was a Homeopath. And I really didn't know just what part I should take in this matter. The only thing I could see to do was to consult Dr. Ogden and Dr. Hutchinson, the two top men on the City and County Hospital Staff and also Homeopathic doctors. After their discussion they advised me to stand by the interns, if I thought they would do the same for me in a similar case. There was no question in my mind that my fellow interns would do the same for me. They agreed with me and said, "go ahead." So I went out, not on my own hook but with considered advice from the two biggest men on the staff. Whether they reasoned that we were so close to the end of our internship and it didn't matter, or that maybe this would show Dr. Ancker he couldn't always get away with acting the part of an unreasonable dictator, I don't know. But I do know they didn't think it was wrong on my part.

Dr. Ancker stood his ground and we all left two weeks early. There wasn't a hitch in services for the sick and I doubt that a patient was even aware we were gone. There was no hardship for the hospital for Dr. Ancker just called the next class of interns in two weeks early. But the newspapers slanted their story that we were ungrateful kids and we had no honor.

We all had our M.D. degrees when we came for our internship and as I said before we didn't need the internship to practice.

The whole incident made me ashamed, so

“All Registered Nurses are Alike”

It stands to reason. They all go through the same training; they all have to pass the same tests; they all have to measure up to the same standards. Therefore, all registered nurses are alike.

That’s nonsense, of course. But it’s no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer’s standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn’t so.

You might also say that all registered nurses aren’t alike, either.

BAYER
ASPIRIN
FOR
CHILDREN

later I wrote a letter of apology to Dr. Ancker. I didn't want to have him think too hard of me. While I had gone out with the fellows, I had not done it in a fit of temper, but with considered judgment of highly respected physicians in St. Paul. Nothing ever came of it, but I wanted to set the record straight between Dr. Ancker and myself.

The marriage of City and County Hospital and Dr. Ancker went on and on for a total of forty years. When he died on May 15th, 1923, he was eulogized in every twin city newspaper and many of the national medical journals. He had built the City and County Hospital into a top respected position, recognized by medical schools as an outstanding teaching hospital. He was considered an architect of hospitals from his personal experience and from the many articles and speeches he had made about building such institutions. He had been a president of the American Hospital Association and at the time of his death he was on the editorial board of *Hospital Management.*

He literally died "in the harness," for he was making rounds in the hospital, and the story goes he still was in his usual form when he exploded in the surgeon's washroom because he thought the surgical interns were not getting their hands clean enough for surgery. He returned to his office to prepare a talk for the local medical society when he collapsed and died of a coronary attack.

Shortly after, the City and County Hospital name was changed to Ancker Hospital in his honor and Ancker Hospital it has been known for the past forty years.

Pediatrics: Yesterday, Today, and Tomorrow

The Emergence of Chronic Diseases as Management Problems of Childhood

Pediatrics Past

THE DEVELOPMENT of present medical knowledge is the product of the translation of basic research findings into practical application as well as the result of stimulation for incisive investigations prompted by astute clinicians.

A bidirectional flow of concepts and ideas from the research laboratory to the patient and from the bedside to the investigator has produced vast strides in man's attempts to eradicate disease. The discerning observations of Jenner,[1] and of Chain and co-workers,[2] and the application of the basic viral culture techniques of Enders, Weller, and Robbins,[3] Salk,[4] Sabin,[5] and others are pertinent examples of such effective translations.

Some of the diagnostic and therapeutic challenges of a generation ago are now among the roundsmanship repertoire of the junior medical student. However, as a result of recent advances in medicine, it is not unusual to find a student, intern, or resident who has never seen a diphtheritic membrane or heard the characteristic "Whoop" of pertussis. The bedside vigil with the bulbar poliomyelitis patient is fortunately no longer the virtually helpless task it was slightly more than a decade ago. Bacterial pneumonia, otitis media, diarrhea, and venereal disease no longer threaten the infant as they did a generation past. Meningitis, treacherous though it remains, is no longer associated with the almost universal fatality of the preantibiotic era. Acute infectious diseases, so serious in the age of our own childhood, now yield in large measure to a variety of antimicrobial agents. The premature, or immature infant, having escaped the iatrogenic insults of hyperoxygenation, vitamin K, and sulfa drugs, now faces a greater chance of survival, with subsequent normal growth and development, than ever before. Formula manipulations have been responsible for serious metabolic disturbances in infants.

FOR YOUR ELDERLY ARTHRITIC PATIENTS...

an effective
GERIATRIC
antiarthritic
with
REASSURING SAFETY FACTORS

Effectiveness, dependability and reassuring Safety Factors make PABALATE-SF a logical choice for antiarthritic therapy in elderly patients—even when osteoporosis, hypertension, edema, peptic ulcer, cardiac damage, latent chronic infection and other common geriatric conditions are present. The potassium salts of PABALATE-SF cannot contribute to sodium retention...the enteric coating assures gastric tolerance...and clinical experience shows that this preparation does not precipitate the serious reactions often associated with corticosteroids or pyrazolone derivatives.

Side Effects: Occasionally, mild salicylism may occur, but it responds readily to adjustment of dosage. Precaution: In the presence of severe renal impairment, care should be taken to avoid accumulation of salicylate and PABA. Contraindicated: An hypersensitivity to any component.

Also available: PABALATE—when sodium salts are permissible. PABALATE-HC—Pabalate-SF with hydrocortisone.

Pabalate®-SF

A. H. ROBINS CO., INC., RICHMOND 20, VIRGINIA

In each persian-rose enteric-coated tablet: potassium salicylate 0.3 Gm., potassium aminobenzoate 0.3 Gm., ascorbic acid 50.0 mg.

—the new, convenient way to prescribe
PABALATE-SODIUM FREE

These tragic good intentions from the past should focus our attention on Hippocrates' dictum, "do no harm," and serve to continually warn us that the "remedy" may be worse than the disease.* The thalidomide tragedy is a poignant example of this error; and today there is some evidence to suggest that perhaps routine vaccination for smallpox should be discontinued in the United States.[6]

Thus, pediatrics yesterday was characterized by a high mortality rate from acute infectious diseases, frequent morbidity with prematurity, vitamin deficiencies, and the lack of modern surgical techniques. Effective vaccines, potent antimicrobial agents, a virtual vitamin "fall out," and corrective surgery have significantly reduced these problems. The multidisciplined team approach composed of surgeons, anesthesiologists, electronic engineers, physiologists, biochemists, and scientific instrument technicians have made possible cardiopulmonary, ophthalmologic, and neurosurgical procedures which were considered impossible a decade or two ago. Today a wide variety of congenital defects of infancy are amenable to corrective surgery. Continued application of basic virological techniques provides the means of rendering extinct rubeola and, hopefully, other viral diseases. Human serum or gamma globulin, hyperimmune for various diseases, including tetanus and possibly rabies, promises to eliminate the necessity for having to choose between the lesser of two evils when, for example, the physician is faced with the choice of the risk of tetanus or the high frequency of serum sickness.

Pediatrics Present

Improved prenatal care and obstetrical techniques have contributed much to the armamentarium required for the accomplishment of gestation in many mothers. Pediatrics today, however, faces a new kind of challenge — accidental death and poisoning. Again, attempts to be "helpful," i.e., inviting and attractive products and packaging, have resulted in the ingestion of toxic household agents such as floor wax and cleaning fluids. Our pharmaceutical colleagues now supply us with the most appealing and palatable medicines ever devised — a far cry indeed from the days of sulfur and molasses. With such delicious products, is it any wonder then that "flavored baby aspirin" repeatedly occupies such a high rating on the list of poisons ingested by children?

Additional hazards which face the child of today are related to our changing sociologic structure. The maternal deprivation syndrome, the fatherless child, and the battered child pose difficulties in understanding and complexities in management sufficient to require a modern Solomon for solution. Certain it is that the pediatrician of today must assume a more "social" role as a member of the physician-patient-parent-school group interested in good health for all children.

The Complete Pediatrician

Pediatrics today requires an even greater utilization of the basic biochemistry and physiology so often committed to oblivion by the sophomore medical student following final examination. Successful management of disturbances in amino-acid and carbohydrate metabolism associated with mental deficiency demand not only prompt clinical suspicion and diagnosis but also continued application of basic physiological chemistry, including nutrition in its broadest aspects.

The pediatrician of the '60s, if committed to the holistic** approach to child health, finds his patient-care time reduced by meetings and conferences, often involving members of other disciplines. For instance, the period of time required for "staffing" the post-rubella infant of an unwed mother presents multiple demands, with planning conceivably for the participation of an ophthalmologist, a pediatric cardiologist, and an otolaryngologist, plus a retinue of speech pathologists, occupational and physical therapists, social workers and others necessary to fulfill the total "habilitation" of the child and mother. The direction and speed with which these forces interact insofar as the infant is concerned should be guided by a knowledgable pediatrician. An improvement in the capacity of the physician to deal more productively with these patients and their prob-

to help relieve pain in common anorectal disorders

"non-caine"

Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form...both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.

DIOTHANE®
OINTMENT
CHILL
PULL APART

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

Merrell

THE WM. S. MERRELL COMPANY
Division of Richardson-Merrell Inc.
Cincinnati, Ohio 45215/Weston, Ontario

lems is clearly in order. More efficient utilization of ancillary personnel and reorientation of the management of these children in keeping with changing concepts of total care are certainly an important step. Perhaps medical students of today are made more aware of these problems than today's pediatricians were during their education (reference personal).

There exists today a suppositional "super highway" to health. It is intended for unidirectional traffic, although rare iatrogenic reversals are to be seen, e.g., complications associated with vaccination against smallpox. It is this road which we now explore in relation to the pediatrics of tomorrow.

Pediatrics Henceforth

Mortality statistics of the premature and neonate have slowly declined. Increasing fetal salvage, understanding the mechanism initiating labor, and elucidating the pathogenesis of teratology* will so broaden this "highway" that many now "crowded off" early in life will survive. Surgical techniques and instrumentation geared to the exigencies of the immature infant and newborn will further decrease mortality associated with congenital defects — the leading cause of death in the neonate.

Diseases characterized by chronicity will assume greater importance in terms of relative frequency as more attention is directed toward the areas of mental retardation, neurological handicaps, rheumatoid arthritis, and chronic renal disease.

The pediatrician may find that his course is frequently detoured as other disciplines become responsible for areas of patient care. He must remain responsible, however, for the programming of ongoing care, and should avoid the temptation to abdicate, expensive as this may become, as far as expenditure of time is concerned. More and more children will indeed require larger and larger units of attention, and parents will deserve comparable periods for explanation and planning. To some extent the pediatrician will be involved in these sessions.

Rheumatoid arthritis, chronic renal diseases, mental retardation, and neurologically handicapping disorders, must have the same "access rights" to this "highway to health" that have been granted to the polio community — a hamlet now virtually extinct. Current research programs give promise of widening and shortening "access routes" for these somewhat forgotten children.

Rheumatoid arthritis appears to represent an infectious process, and if this is true, appropriate antimicrobial therapy should be possible. Until this is proven, however, physiotherapy, encouragement, and proper medical management must suffice.

The judicious use of corticosteroids to facilitate physiotherapy is occasionally required, but salicylates and hydrotherapy usually control joint involvement. It is imperative to consider the nature of the disease — it is crippling, not killing — and tragic consequences attend the overenthusiastic use of steroids, transfusions, or salicylates. The physician must supply a supportive role and accept along with the patient the chronic, undulating course rheumatoid arthritis pursues.

Chronic renal disease, secondary to acute glomerulonephritis and diabetes mellitus, or of unknown etiology, presents a less hopeful situation. Azotemia, anemia, and ultimate death are now all too common; yet in the practice of tomorrow consideration of the multiple facets of organ transplantation will be necessary. The sacrifice of a kidney from a healthy donor — mother, sibling, or other relative — should be associated with a great deal of counseling of all parties concerned.

The Mentally Handicapped

The problems of children with mental retardation and neurological handicaps will be responsible for a shift of emphasis towards "maximum stimulation" of the individual's potential for development during the pediatric years of life. Unfortunately, an apathetic attitude on the part of some physicians is encountered by parents when their mentally deficient children are examined; an attitude that must improve to encompass hopefully all the advances modern medicine has to offer. There will be an increased need for pediatricians devoted to this particular type

of patient, as the image of mental retardation emerges from the hidden, secretive aura of the last century into a more enlightened, understanding era, in which shame on the part of parents yields to eagerness to know more about the causes of retardation. Groups of parents to whom the pediatrician can relate freely may be an effective means of public education. Quite likely an increasing proportion of mentally retarded infants will be cared for in the home. The physician, therefore, may expect to see more of these patients who formerly might have been committed to state institutions in the neonatal period.

Pediatrics must meet the challenges inherent in the education of medical students, interns and residents, and in the postgraduate programs for other physicians. Participation in teaching activities is a stimulating and rewarding experience, and pediatricians have no less to offer than the surgeon, internist, or any other physician dedicated to imparting knowledge.

At this hospital we are pledged to continue this vital role of education. Pediatrics tomorrow will represent a reflection of the data, the clinical acumen, the thirst for knowledge, and the motivation to provide succor for children.

Finally, pediatrics tomorrow must continue to reflect the dedication of physicians of these and yesteryears, whose devotion to the growth and development of children has prompted many of these great advances along the "highway of health."

Homer D. Venters, Jr., M.D.*

Gardner's Syndrome

THE PATIENT of Doctors Shook and Windschitl* who has Gardner's syndrome clearly demonstrates the need for familiarity with syndromes. While our knowledge of many is extremely inchoate, nevertheless, there is a moral responsibility to recognize the signs of at least the most serious ones.

The infrequency with which this syndrome is reported does not reflect its true incidence. Incomplete physical examination, especially by dental, facial, and cranial roentgenography, the attempt at brevity in case reports, and the purposeful deletion from scientific papers of what appear to be incidental findings (epidermoid cysts, fibromas, osteomas, odontomas, etc.) are factors that may be responsible for their failure to be recorded.

Knowledge of the existence of this syndrome adds immense importance to the "incidental findings," for one facet or more almost always precedes the clinical manifestations of intestinal polyposis. The presence of multiple epidermoid inclusion cysts, fibromas, desmoids, or bony growths, especially of the facial skeleton, should lead to a complete search for the intestinal component. Recording of these incidental findings should be just as mandatory as roentgenographic search for additional intestinal polyps if a single rectal polyp is detected. The discovery of multiple polyps, or of any other component, also places responsibility upon the investigator to search other relatives thoroughly for the stigmata. Because a negative report does not mean that polyps or the

at Merck Sharp & Dohme...

understanding... precedes development

The development of chlorothiazide and probenecid were events of major importance, but perhaps even more important for the future was the Renal Research Program by which they were developed. When Merck Sharp & Dohme organized this program in 1943, it was expressing in action some of its basic beliefs about research:

- Many problems connected with renal structure and function were still undefined or unsolved. The Renal Research Program would begin its basic research in some of these problem areas.
- From knowledge thus acquired might come clues to the development of new therapeutic agents of significant value to the physician.

For example, the Renal Research Program put fifteen years into this search before chlorothiazide became available. But because these years had first led to a greater understanding of basic problems, the desired criteria for chlorothiazide existed before the drug was developed.

Along with other research teams at Merck Sharp & Dohme, the Renal Research Program continues to add new understanding of basic problems—understanding which will lead to important new therapeutic agents.

MSD MERCK SHARP & DOHME Division of Merck & Co., Inc., West Point, Pa.

where today's theory is tomorrow's therapy

other components will not appear in future years, periodic re-examination of all persons with a parent who had one or more of the stigmata is necessary. It is also important to inform the patient of the legacy with which he may endow his descendants and the possibility of the existence of the syndrome in his siblings.

Other syndromes may also be cited to emphasize this point. Labial and oral mucosal papillomatosis accompanied by papillomatosis and pigmentation of the axilla, neck and groin signify the development of gastric cancer (malignant acanthosis nigricans). Multiple melanotic spots around and in the mouth, on the eyelids and around the nostrils may signify nonmalignant intestinal polyposis which can cause intussusception and intestinal obstruction (Peutz-Jeghers Syndrome*). Obscure signs as bifid rib, kyphoscoliosis,* falx calcification and multiple cysts of the jaw bones may be associated with multiple basal cell cancers of the skin. Bowen's disease of the skin and dermatomyositis are associated with a higher incidence of internal malignancy.

Mitral Insufficiency with Coronary Disease

THERE ARE many ways in which the cardiac alterations in coronary disease can produce mitral insufficiency. Left ventricular enlargement in cardiac decompensation often is associated with a systolic murmur which later disappears coincident with compensation and reduction in heart size. There are many explanations for this evanescent murmur, including mitral annular enlargement and papillary muscle dislocation. Burchell and Brown[1] describe an unusual (possibly unique) association of mitral insufficiency and coronary disease in a 14-year-old boy submitted to surgery for mitral insufficiency. Anomalous coronary circulation was found five months later at autopsy. The left coronary artery arose from the pulmonary artery.

With myocardial infarction associated complications can cause mitral insufficiency. A left ventricular mural thrombus can interfere with the seating of the valve. Ventricular aneurysm can dislocate papillary muscles and attached valve leaflets. The papillary muscle may be involved in the infarct. Rupture of a papillary muscle is a well recognized complication. The effect of papillary muscle dysfunction without rupture has been recently described in this issue.* Burns and Layman report a case of this type with mitral insufficiency caused by infarcted papillary muscles. The valvular complications of papillary muscle infarction have been emphasized by Burch et al.[2] Burch's group has described an electrocardiographic "syndrome" of infarction of the left anterolateral papillary muscle. They emphasize S-T interval and T wave changes in the left precordial leads with junctional depression of the S-T segment. Electrocardiographic changes in these leads are very common, however, and their suggestion of a "syndrome" which may be diagnostic of papillary muscle involvement remains to be confirmed. In the case described by Burns and Layman electrocardiographic features were not diagnostic.

The subendocardial regions are the distal areas of myocardial circulation and the first to succumb to inadequate circulation. The papillary muscular increscences from the subendocardium are terminal areas whose circulation should be most readily compromised.

Myocardial infarction occurring in the presence of severe mitral (or other valve) disease raises formidable diagnostic problems. Every symptom, sign, or finding of the infarct may be attributed to the valvular disease or to myocardial alteration produced by the orificial problem. The surgeon remov-

Stress formula vitamins are an important supportive measure in maintaining the nutritional status of the emotionally disturbed patient. With STRESSCAPS, B and C vitamins are present in therapeutic amounts to meet increased metabolic demands. Patients with anxiety, and many others undergoing physiologic stress, may benefit from vitamin therapy with STRESSCAPS.

STRESSCAPS® FOR PROFESSIONAL RECOMMENDATION ONLY

Stress Formula Vitamins Lederle

Each capsule contains:

Vitamin B_1 (as Thiamine Mononitrate)	10 mg.
Vitamin B_2 (Riboflavin)	10 mg.
Niacinamide	100 mg.
Vitamin C (Ascorbic Acid)	300 mg.
Vitamin B_6 (Pyridoxine HCl)	2 mg.
Vitamin B_{12} Crystalline	4 mcgm.
Calcium Pantothenate	20 mg.

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 and 100; bottles of 500.

Lederle LEDERLE LABORATORIES, A Division of AMERICAN CYANAMID COMPANY, Pearl River, N. Y.

ing the mitral valve apparatus for replacement with an artificial valve will occasionally be surprised to find an infarcted papillary muscle. This occurred in a 54-year-old man with mitral stenosis and insufficiency.[5]

Surgery of mitral incompetence so far has been concerned largely with rheumatic defects. Corrective procedures may also be possible in a papillary muscular problem. Direct papillary muscle repair has been reported in two cases from the Minneapolis Veterans Administration Hospital by Adicoff et al.[3] Both died in the immediate postoperative period. Prosthetic valves may be considered when intractable heart failure is thought to be due principally to the valve incompetence. However, as Holloway et al.[4] point out, the prognosis must be poor due to the inadequate coronary circulation and the likelihood of further infarction.

Heart Failure in Pediatrics*

IN THE pediatric age group congenital heart disease is the most common cause of heart failure. Infancy is the age when it is most prevalent and when most deaths occur. In past decades rheumatic fever was in the vanguard as a cause of cardiac failure in pediatrics. This disease has become more mild in its manner of occurrence, and its prevention by adequately treating streptococcal disease has made it second in importance to congenital heart disease as a cause of heart failure.

Modern surgery has made possible the salvation of many patients born with congenitally defective hearts. The recognition of the existence of congenital heart disease and the exact definition of the nature of the problem before the patient is in serious trouble are essential to successful outcome. This is particularly true of the infant. In this age group time between first symptoms and death may be very short. Medical treatment should be given but a brief trial and diagnostic procedures carried out concurrently. Severe pulmonary stenosis, aortic stenosis, and coarctation of the aorta are examples of conditions that sometimes require surgical relief soon after symptoms occur if death is to be prevented. Diagnostic procedures can be carried out safely on infants and even newborns. Ignorance of the nature of a problem may be a much greater risk.

When heart failure does occur, it doesn't necessarily mean disaster. Many patients, especially those with left-sided lesions, for example coarctation of the aorta, may be tided over until a time when surgery can be more safely carried out. The recognition of heart failure in infancy and early childhood is sometimes difficult. The classical signs of pulmonary rales, hepatomegaly, and pulmonary edema frequently are absent. Rapid breathing and persistent wheezing often are the only findings. Hyperpnea may be paroxysmal. It may be evident only on exertion. Fatigue during nursing and a longer nursing time may be important historical facts brought forth by the mother. Physical signs that are thought to suggest asthma or bronchitis may be caused by heart failure.

Digitalis in all forms is generally well tolerated in rather large doses by pediatric patients. Notable exceptions are the premature and the newborn infant. Fatalities from

You've Made Us Change

APACHE MEDICAL COMPLEX

We started with plans for the most modern, most efficient, most tenant-oriented *medium-sized* medical complex in Minnesota. Your response forced us to change our plans. Now we're going to construct the most modern, most efficient, most tenant-oriented *large-sized* medical complex in Minnesota, to be built at Apache Plaza in two medium-sized stages. Stage 1, pictured above, will be ready for you in Fall, 1966.

Here are some of the reasons why Apache Medical Complex will be the ideal location for your new office:

digitoxicity in these patients are thought to go unrecognized since dysrhythmias are commonly the only manifestation and are recognized primarily by the electrocardiogram. Adherence to the dosage schedule suggested by Doctor Lade in this issue* and frequent evaluation of the electrocardiogram can prevent fatalities. Lanatoside C, Cedilanid, is a more rapid acting glycoside than Lanoxin and there is an advantage in giving the glycoside intravenously to the patient in severe heart failure. Capillary stasis accompanies heart failure and impedes the absorption of digitalis when given intramuscularly or subcutaneously.

Mistakes in calculating the volume of injectible digitalis may be avoided by dilution of the drug and by the use of a tuberculin syringe. Physician attention to these details may help pediatric nurses avoid fatal errors and upgrade the accuracy of administration of other drugs.

Butazolidin® alka

Each capsule contains:	
Butazolidin, brand of phenylbutazone	100 mg.
dried aluminum, hydroxide gel	100 mg.
magnesium trisilicate	150 mg.
homatropine methylbromide	1.25 mg.

in painful shoulder

Geigy

Therapeutic Effects
The acute phase of subdeltoid bursitis, tendinitis and associated periarticular inflammation usually responds promptly and dramatically to phenylbutazone. Pain and tenderness may be relieved within 24-48 hours and mobility of the affected arm quickly restored. Full recovery is frequently achieved within 7-10 days so that therapy is generally of short duration. Calcific deposits are not specifically affected by treatment, but their presence does not appear to retard symptomatic improvement.

Phenylbutazone has not replaced physiotherapy, x-ray treatment, or local injections of hydrocortisone in the more chronic conditions, but it may advantageously be combined with these measures.

Contraindications
Edema, danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. Because of the increased possibility of toxic reactions, the drug should not be given when the patient is senile, or when other potent chemotherapeutic agents are given concurrently. Large doses of Butazolidin alka are contraindicated in patients with glaucoma.

Precautions
Before prescribing, the physician should obtain a detailed history and perform a complete physical and laboratory examination, including a blood count. The patient should be kept under close supervision and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools. Regular blood counts should be made. The drug should be used with greater care in the elderly.

Warning
If coumarin-type anticoagulants are given simultaneously, the physician should watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea and sulfonamide-type agents and insulin. Patients receiving such concomitant therapy should be carefully observed for this effect.

Adverse Reactions
The most common adverse reactions are nausea, edema and drug rash. The drug may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, generalized allergic reaction, stomatitis, salivary gland enlargement, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia are also possible side effects. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently.

Average Dosage
Initially, give 400 mg. daily (one capsule q.i.d), reducing this, if possible, when a favorable therapeutic effect has been obtained. If after one week there has been no response, discontinue the drug. Butazolidin alka contains antacids and an antispasmodic to minimize gastric upset.

Note: The physician should be fully aware of dosage, precautions, adverse reactions, and contraindications as contained in the complete prescribing information.

Also available:
Butazolidin®
brand of phenylbutazone
Tablets of 100 mg.

Division of Geigy Chemical Corporation
Ardsley, New York

Letter to the Editor:

We are not fooling. We have recently lost two competent physicians in Roseau who have gone away to specialize "for more time off and other benefits." We are really hurting and, I suppose, building up potential coronary disease from lack of sleep and constant jangling of the phone, office and hospital pressure, and from the ever increasing paper work which robs us of the few leisure moments we might otherwise grab.

I think the time is urgent for a crash program to produce more good highly trained general practitioners for the rural and suburban areas. There will always be plenty of specialists and researchers even though the medical schools seem to think otherwise —

Jack Delmore, M.D.
Roseau, Minnesota

Editor's Note: Dr. Delmore's distress call could not be more poignantly stated. Many others have expressed a similar view. At the expense of utter exhaustion no ethical doctor will ever shirk his duty to his patient. He will not prescribe or operate unnecessarily. He will not substantiate unjust claims against the numerous government and insurance guarantors who seem to be ever increasing their demands for superfluous paper work, nor will he perjure himself or the honorable profession of medicine by making charges that are not commensurate with the services rendered. On the other hand, as long as our country remains free from dictators or dynasties, he will not consent to be assigned to a location in Toonerville where he must of necessity be required to revert to the primitive practice of grandfather's day, because he knows that without honorable, ethical, highgrade, modern medicine only the patient suffers.

The Editor's Soliloquy

Cuneiform Symbols

If you have ever tried to read the longhand notes of most physicians on hospital records, you can readily appreciate the difficulty archaeologists encountered deciphering the prescriptions written on stone in cuneiform symbols during the third dynasty of Ur in the year 2100 B.C.

Now realizing these earlier difficulties, some modern hospitals, apparently with the intention of preserving their obsolete records for some archaeologist of the 60th century, have instituted the use of a dictating-typing service whereby doctors' notes can be transcribed into uniformly readable records to repose in and augment future medical archives.

Even though the project would involve the elimination of fascinating, but withal baffling, individualistic graphologies, the common denominator of legibility would be well worth the sacrifice.

Without such a transcription service how would future archaeologists decipher the numerous chirographies encountered in present medical records: the strabismic micrography of U. S. H., the gargantuan macrography of V. L. H., the execrable cacography of H. B., and the exasperating haplography of H. W. O. Of course those 60th century archivists et al. would have no trouble whatsoever perusing the delightful calligraphy appearing above the initials C. O. R.

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Miltown® (meprobamate)

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its anti-anxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

WALLACE LABORATORIES
Cranbury, N.J.

CM-5761

Curbstone Consultation

Drug Sensitivity Hepatitis

QUESTION: Is the drug sensitivity hepatitis amenable to any specific type of therapy?

ANSWER: The first principle of therapy is recognition of the drug-induced nature of the hepatic injury followed by withdrawal of the drug. For cholestatic reactions such as those produced by sulfonylurea compounds such as chlorpromazine or anabolic steroids, further therapy is usually not needed. If pruritus is severe, cholestyramine will be of some help when it becomes available. Periactin 4 mg. q.i.d. may also be helpful. In general, patience, on the part of the patient and also the doctor, is what is needed most. The role of bed rest has yet to be evaluated in this condition, but some restriction of activity seems reasonable. The viral hepatitis-like reaction seen with monoamine oxidase inhibitors and now being reported with halothane is treated like any severe viral hepatitis with cortico-steroid therapy if the patient becomes very ill.

Fenton Schaffner, M.D.
Mt. Sinai Hospital
New York, New York

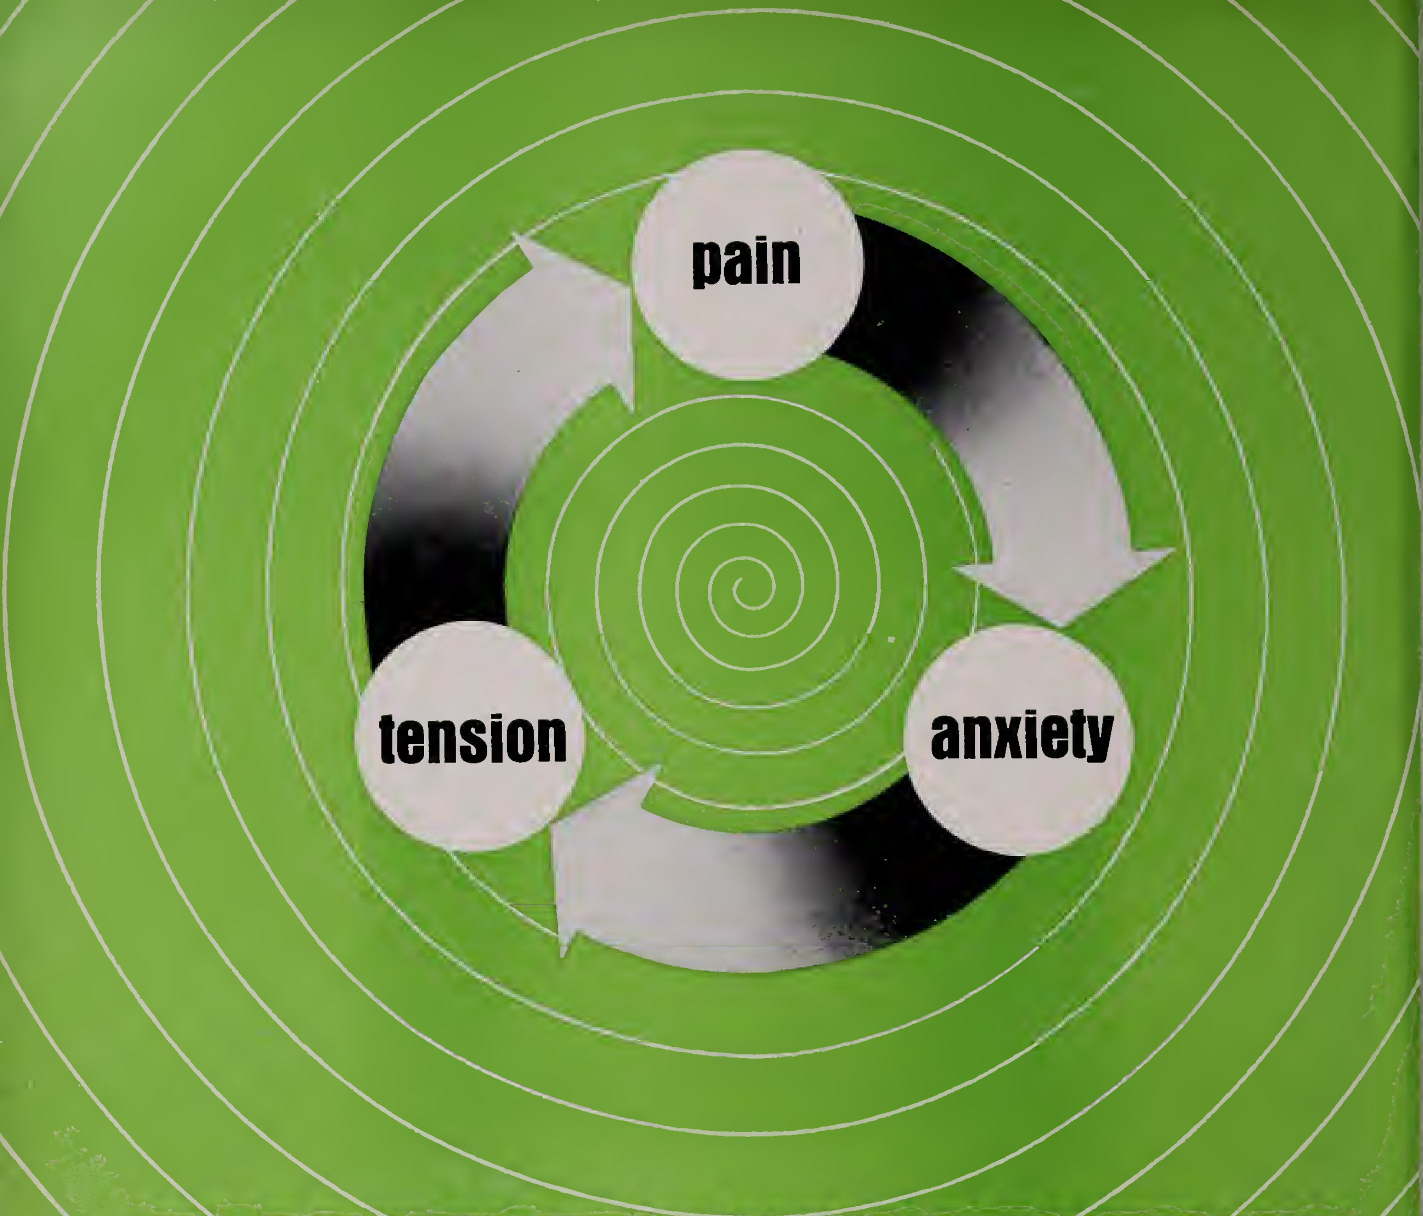
Progestin-Estrogen

QUESTION: Do you have any method of selecting suitable cases of acne which will respond favorably to the progestin-estrogen drug therapy?

ANSWER: I do not believe this type of therapy should be used as routine. Many female patients with acne will respond to the more conventionally used types of therapy and do not necessitate the use of hormones. We reserve hormone therapy for those patients who have not responded to a more conservative approach, including the use of acne surgery, topical medications and antibiotics. Naturally, the patients that are selected are among those who are in their upper teens or early twenties.

John S. Strauss, M.D.
Associate Professor
Boston University
Boston, Mass.

"The value of a gift lies not so much in the price tag as in the love tag." — Dr. E. O.



for the comprehensive control of the pain cycle

TRANCO-GESIC®

CHLORMEZANONE with ASPIRIN

100 mg. 300 mg.

NON-NARCOTIC ANALGESIC, with tranquilizing and muscle relaxant properties

Because pain is frequently aggravated and perpetuated by both anxiety and muscular tension, the combination of aspirin with a well tolerated tranquilizer—muscle relaxant (Trancopal® (brand of chlormezanone)) is exceptionally effective.

TRANCOPAL is a "Tranquilaxant" which calms anxiety and tension, relieves muscle spasm, and enhances the analgesic effect of aspirin by subduing *emotional responses* to pain.

In low back pain

sciatica, lumbago; musculoskeletal pain associated with strains and sprains

In tension headache

premenstrual tension and dysmenorrhea

Side effects such as gastric distress, occasional weakness, sedation or dizziness may be noted. Ordinarily, these may be reversed by a reduction in dosage or temporary withdrawal of the drug. TRANCO-GESIC should not be administered to persons known or suspected to have an idiosyncrasy to acetylsalicylic acid.

Dosage for adults is usually 2 tablets three or four times daily, the suggested dosage for children from 5 to 12 years is 1 tablet three or four times daily.

Supplied in bottles of 100 and 1000 tablets.

Winthrop Laboratories
New York, N. Y. 10016

Fracture–Trauma Conference

Management of the Acutely Injured Patient

The highest mortality among acutely injured patients occurs within the first few hours following injury. Therefore the initial evaluation and treatment of these patients is critical if deaths are to be prevented.

Although many patients with massive injuries involving aortic and/or myocardial disruption, head injuries, or liver rupture die prior to their reaching medical help, yet other pateints with similarly massive injuries may still be alive and therefore potentially salvageable at the time of their arrival at a medical facility. Pertinent evaluation and treatment must be rapidly initiated to help this type of patient. A report from the rescue personnel should be filed, including mode of injury, initial and subsequent changes in level of consciousness, treatment given, and estimated prior blood loss including that at the accident scene.

Dangers of Mobilization

Active or passive motion of the acutely injured patient is to be avoided for several reasons.

Loss of Blood Volume

A patient may lose up to 20% of his blood volume and through compensatory vasoconstriction and selective circulation maintain a relatively normal measurable arterial pressure. The seemingly minor further trauma of transfer to an x-ray table may initiate profound shock in such a patient.

Hypotension

Further bleeding at fracture sites or from ruptured viscera occasioned by even slight motion of the patient may similarly produce severe hypotension with resultant myocardial and cerebral damage. Pelvic fractures, occult and unsuspected prior to x-ray examination, are particularly treacherous in this regard. Hauser[1] has shown the massive and often lethal occult bleeding that can occur in these circumstances. Even passive motion of these patients may initiate further massive unobserved blood losses.

Continued

Transection of Cord

Unsuspected spine fracture-dislocations may on motion be converted from an asymptomatic spinal cord contusion to a complete and permanent cord transection. Therefore we routinely place each acutely injured patient at admission on a radiolucent rigid litter (Fig. 1) developed at the Ancker Hospital.[2] Extremity fractures are stabilized by constant traction, and the head is stabilized by laterally placed sand-bag supports. The patient is maintained continuously on this litter throughout his initial evaluation, x-ray studies and early treatment, be it supportive observation or emergency surgical procedure.

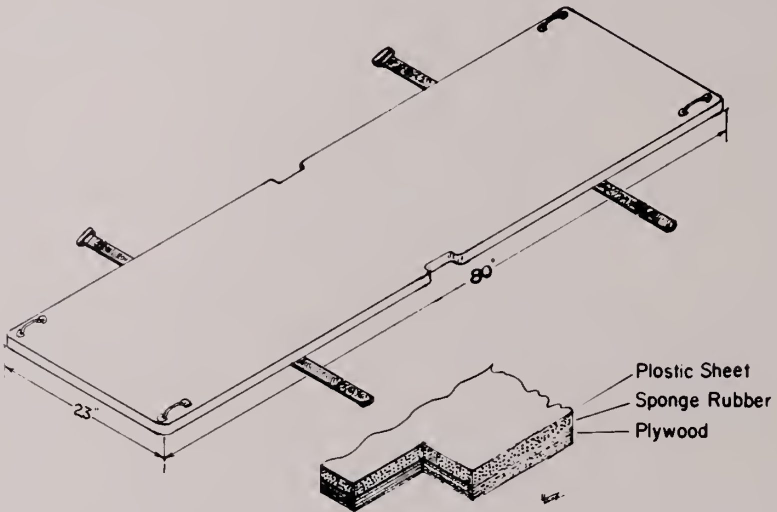

Fig. 1 — Diagram of Receiving Room litter employed at Ancker Hospital.

Correct Respiratory Insufficiency

Initial evaluation of the acutely injured patient must include observation for respiratory distress, cardiac arrest, shock and brain injury. Assignment of priority of treatment usually goes first to respiratory insufficiency, be it of neurological, intrabronchial or extrabronchial origin, because such insufficiency is least well tolerated and must be corrected before any of the following problems can be treated. In close succession follow cardiac arrest, hemorrhagic shock and head injuries, with extremity fractures usually of least initial risk.

Open Airway

The patient's upper and lower respiratory tract is cleared by suction, an oral airway inserted and ventilatory support given by the best method at hand, such as a face mask and a device for administering positive pressure intermittently. This measure failing, insertion of an endotracheal tube may prove necessary; but such a maneuver may cause dangerous delay in pursuit of more urgent matters and should not be done routinely.

Prevent Pneumothorax

Sucking chest wounds should be completely occluded with a vaseline gauze dressing and a chest tube inserted for suction until the patient's vital signs are stable and his total injuries known, when definitive debridement and closure are propitious. Physical signs of a pneumo-and/or hydrothorax are indication for confirmatory thoracentesis, whereupon a large chest catheter should be placed and connected to suction. This maneuver, of very low immediate or long-term risk, prevents the formation of an occult massive pneumothorax or hemothorax when attention may be diverted to another problem. Moreover it allows monitoring of blood losses within the chest. The presence of an unstable area of chest wall with paradoxical respiratory motion — a "flail" chest — is an indication for prompt insertion of a chest tube for suction, performance of a tracheostomy, and positive pressure respiratory assistance. Pulmonary edema will reward delay in this.

Emergent Treatment

Simultaneously the patient's pulse is monitored digitally to detect an unusual or absent cardiac rate. Closed chest massage must be promptly performed for cardiac arrest, all the while its inciting cause being sought and corrected. The rigid litter is ideal for this technique. Arterial blood pressure should be monitored by an arm cuff.

Intravenous

An intravenous drip through a large-bore needle must be placed in an arm or leg vein or both as early as possible, enabling recovery of a blood specimen for typing and cross-matching, and providing constant access to the vascular system not only for the emergency administration of fluid and blood but also of medication, especially as needed to treat cardiac arrest. Moreover, the peripheral venous pressure can thus also be estimated for guidance in blood replacement. To wait until the intravenous is "needed" is to wait too long.

Transfusion

If the patient is hypotensive and the above needs are fulfilled and of course if blood loss is evident, decreased circulating blood volume may be assumed. Brain injuries as a rule do not cause hypotension. Rapid transfusion of Type O Rh negative whole blood or, as secondary choice, dextran or plasma should be given until cross-matched blood is available or normotension ensues. Such transfusion may be diagnostic as well as therapeutic if a rise in arterial pressure occurs. Recurrence of hypotension would indicate continuing losses of blood. Chest blood losses via the chest tubes will be evident, as will enlarging hematomas about peripheral fractures. Rapid blood loss via chest tubes with persistent hypotension despite multiple transfusions is an urgent indication for immediate thoracotomy. However, in the absence of such obvious blood losses the possibility of occult intra-abdominal hemorrhage from an injured viscus or retroperitoneal blood loss from a fractured pelvis or ruptured bladder must be considered.

Bladder Catheter

A Foley catheter should be passed into the bladder for detection of urinary tract bleeding. A cystogram, performed by simply injecting 100 cc. of 50% Hypaque through the catheter and taking one x-ray of the pelvis — portable x-ray equipment is adequate — and another after the

Continued

bladder is emptied, will show extravasation of dye if the bladder is ruptured. The cystogram should be done as soon as the patient's vital signs are stable or before he undergoes emergency laparotomy. An intact bladder in the presence of gross hematuria is an indication for an emergency intravenous pyelogram.

Laparotomy

If hypotension unaccountably and rapidly recurs despite quick administration of 1500 cc. whole blood, intra-abdominal or retroperitoneal hemorrhage is obviously suspect. Persistent shock, increasing abdominal distension and tenderness predicates immediate laparotomy. Under less urgent diagnostic uncertainties possible intra-abdominal hemorrhage or visceral disruption may be accurately detected by a simple technique of diagnostic peritoneal lavage previously described at Ancker Hospital.[3] A #18-F catheter* with many side holes is introduced into the abdomen via a trocar or stab wound. If no blood or enteric content is obtained by simple aspiration, 1000 cc. of a sterile isotonic saline solution is instilled into the abdominal cavity and then aspirated for examination. It is an extremely sensitive test with no false negative or false positive results reported as yet. Perry[4] found the mortality of blunt abdominal trauma, the only type in which decisions against laparotomy must be made, to be 46%, a large part of which was due to undiagnosed visceral damage and hemorrhage. Since the introduction of this technique at Ancker Hospital there have been no cases of undiagnosed intra-abdominal hemorrhage due to blunt trauma.

Comments and Conclusions

Not until the patient's vital signs are stable should he be transported for complete x-ray evaluation. He is maintained with fractures splinted on the radiolucent litter throughout all x-ray examinations. An acutely injured patient should be accompanied to and attended in the x-ray rooms by a nurse or physician for repeated monitoring of his vital signs. The clinical status of such a patient can change quickly.

While attention has been drawn to the dangers and signs of thoracic and abdominal catastrophes secondary to trauma, so must careful attention be directed to the signs of serious brain injuries such as deepening drowsiness, lateralizing pupil dilatation, and peripheral neurologic deficits. Drainage of subdural or epidural hematomas may be life-saving if not delayed. Unrelenting generalized extensor rigidity, coma, and dilated fixed pupils are usually signs of lethal brain-stem damage.

Tumor Conference

Varix of the Duodenum Simulating Duodenal Tumor*

Pathways of collateral blood flow in portal venous congestion develop primarily at the gastroesophageal junction, the hemorrhoidal veins, and the umbilicus. The purpose of this report is to present a patient with Laennec's cirrhosis* in whom a radiographic duodenal mass was found to be a cluster of dilated veins. A review of the literature has failed to reveal any previous description of such a lesion.

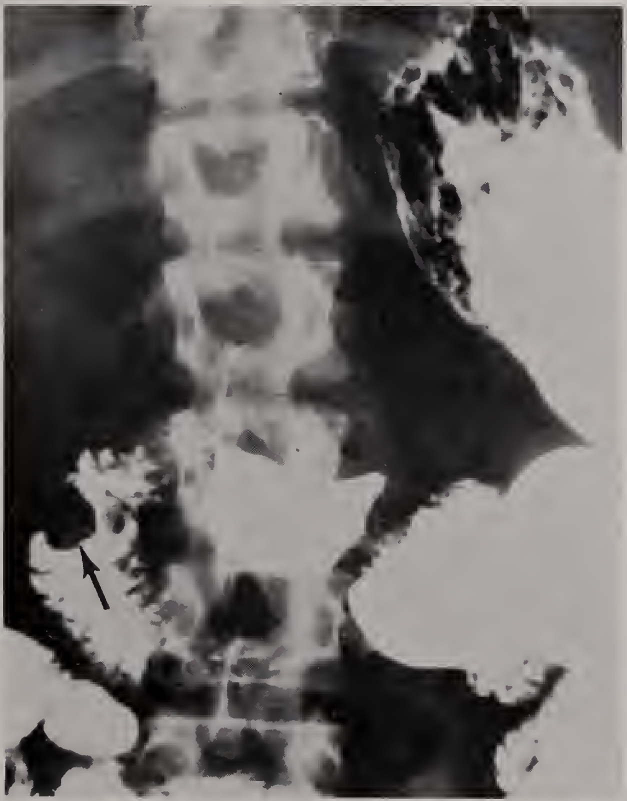

Fig. 1 — Upper gastrointestinal series demonstrating a filling defect (arrow) in the second part of the duodenum in a patient with portal venous congestion. This lesion proved to be a large venous varix.

---

*See Laennec's cirrhosis Page 1503.

Continued

Case Report

A 55-year-old female with a history of alcoholism was admitted to the hospital for the seventh time on March 24, 1965, complaining of progressive weakness and shortness of breath. She was known to have Laennec's cirrhosis and had had upper gastrointestinal bleeding and coma previously. Because of a diffuse patchy infiltrate on the chest radiograph and pulmonary function studies demonstrating an alveolar-capillary block, the patient had a diagnostic lung biopsy. The specimen obtained showed sarcoidosis.

While convalescing from this procedure, the patient was noted to have melena, began to have hematemesis, and subsequently required repeated transfusions. An upper gastrointestinal series showed no evidence of esophageal varices but a filling defect, interpreted as a polypoid tumor, was seen in the second part of the duodenum (Figure 1). A previous gastrointestinal series from 1963 did not show this lesion.

Two weeks after the spontaneous cessation of gastrointestinal bleeding an exploratory laparotomy was performed. The mesenteric veins were dilated and tortuous but esophageal varices were not prominent. The duodenum was mobilized and a group of large dilated veins could be seen on the posterior wall of the second part of the duodenum (Figure 2). The varix simulated a mass in the duodenal wall upon palpation and when visualized intraluminally appeared as a group of veins, 2 x 3 cm. in diameter, covered by duodenal mucosa. There was no active bleeding.

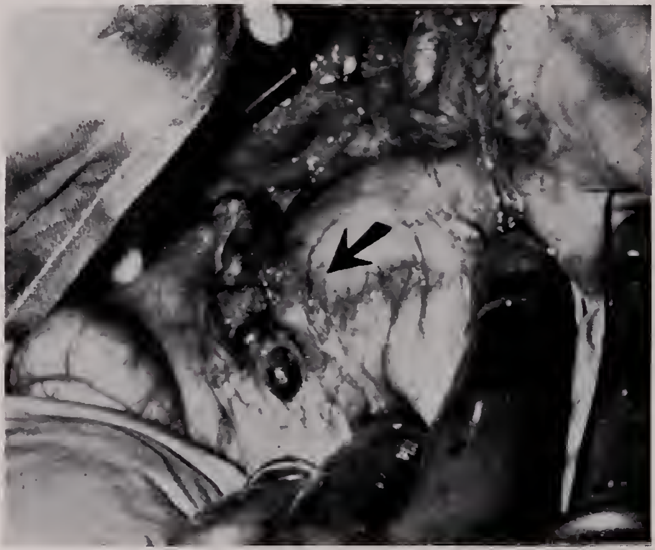

Fig. 2 — Photograph taken at the time of laparotomy in this patient. The duodenum has been mobilized and its descending portion lies just above the surgeon's fingers. The extrinsic part of the varix crosses its posterior aspect (arrow).

Simultaneous measurement of portal and systemic venous pressures revealed a low gradient (portal system = 21 cm. saline, superior vena cava = 10 cm. saline) and a shunting procedure was deemed unnecessary. The varix on the duodenum was thought to constitute a sizable portion of the patient's porto-systemic shunt and was left intact. A vagotomy and gastrojejunostomy were performed to keep the gastric secretions and contents from contacting the lesion. A liver biopsy confirmed the diagnosis of Laennec's cirrhosis.

Discussion

We have been unable to find previous reports of a lesion such as the one described in this patient. Olson et al.,[1] reviewing the radiographic studies in a group of 72 patients with portal venous congestion previously reported by Hallenbeck,[2] found evidence of duodenal deformity in ten. These authors comment on the known association of peptic ulcer disease with hepatic cirrhosis. In their series, however, duodenal deformity was due not to old peptic ulcer disease but rather to compression of the duodenum by dilated venous collaterals. This deformity they describe as occurring about one cm. distal to the pylorus and due to pressure from a dilated posterior superior pancreaticoduodenal vein. The varix found in this case, however, lay in the second portion of the duodenum and does not represent the abnormality described by Olsen although the etiology is probably similar.

Summary

A patient with Laennec's cirrhosis with a duodenal mass is presented. The lesion proved to be a varix caused by portal venous congestion.

Laennec's Cirrhosis*

A multitude of names (Portal cirrhosis, diffuse nodular cirrhosis, atrophic cirrhosis, hobnail liver, alcoholic cirrhosis) have been used to indicate this disease which is a very common type of cirrhosis observed in all parts of the world.

It is most commonly observed following the long continued use of alcohol, although in some countries it is associated with malnutrition, particularly of protein containing the essential amino acids. A deficiency of lipotrophic substances, especially choline, has been shown to produce fatty livers that progressed to cirrhosis in experimental animals. The administration of alcohol to animals has resulted in the production of cirrhosis when combined with high fat diet in prolonged experiments. The changes which are produced in the liver with marked fatty degeneration are common findings in alcoholism. In this stage it is thought that the process is probably reversible if an adequate diet is provided and if the patient abstains from alcohol.

When the fibrosis increases pseudolobules develops and the process becomes irreversible.

Athletic Injuries

The Immediate Management of Abdominal Injuries in Athletics

It is fortunate that abdominal injuries are of infrequent occurrence in athletics, for they are fraught with life-threatening hazard. Football is the only major sport in which there is any significant possibility of abdominal trauma, and even here hip and rib pads protect all but a small portion of the abdomen. Penetrating injuries are so rare, and their management so standardized, that they need no further discussion. The blunt injuries, however, require astute management.

Abdominal injuries of the closed or nonpenetrating type are always difficult to evaluate. Relatively insignificant trauma, affecting only the abdominal wall proper, can cause spasm, guarding, and muscular rigidity which make it almost impossible to rule out deeper and more serious injury to the viscera. As a consequence, in the management of abdominal injuries sustained in athletic activities, one must always err on the conservative side.

An athlete who sustains a blow to the abdomen from which he has not fully recovered after a very few minutes of rest should be taken out of the game and to the locker room. Unlike injuries of the extremities, it is almost impossible to evaluate an abdominal injury on the playing field. Inspection and palpation cannot be adequately performed on the exposed field or court. The injured player should either walk, or be carried to surroundings more conducive to thorough examination.

Inspection of the abdomen, once the injured player has disrobed, may reveal ecchymosis or swelling of some portion of the abdominal wall. Contusions and hematomas of the subcutaneous and muscular layers of the abdominal wall are relatively common, but insignificant. However, when they occur they are frequently associated with tenderness and rigidity, which make it impossible to rule out an underlying injury of a serious nature. In such cases the athlete must refrain from further activity and be kept under careful surveillance until either he gets better or the need for definitive surgery becomes apparent. This may be a matter of hours or even days.

If there is no visual evidence of injury, then a careful palpation of the abdomen should be carried out. The solid organs (liver, spleen and kidney) are most apt to be injured by blunt trauma, but injury to a hollow viscus can occur. The signs associated with the injury depend on the organ involved.

Rupture of a hollow viscus will cause the generalized rigidity associated with peritonitis, and the need for immediate surgery should be obvious. Injuries to solid organs, on the other hand, may not always be associated with prominent symptoms.

Liver injuries, unless they are extensive and include the capsule, may cause only an ill defined tenderness and spasm in the upper abdomen. For this reason even minimal guarding in the liver area requires conservative management and close observation. Increasing hemorrhage or bile leakage from the liver over the next few hours will produce signs and symptoms which warrant laparotomy.

---

*See Minnesota Med 48:1359 for second in this series. Sponsored by Minnesota Committee on Trauma of the American College of Surgeons.

Continued

The findings associated with a torn spleen may be the catastrophic ones of acute hemorrhage. Contusions or small lacerations may produce only minimal findings of tenderness and rigidity in the left upper quadrant. Since delayed rupture of the spleen is common, even minimal left upper quadrant tenderness demands continued rest and observation of the patient.

Kidney injury should be suspected if flank tenderness or discoloration is present. Urinalysis will usually help substantiate the diagnosis.

Injuries to other retroperitoneal organs, or retroperitoneal hemorrhage, though they may not be initially associated with significant abdominal tenderness, will frequently cause vomiting and/or absence of bowel sounds. Even in the face of a relatively innocuous abdominal examination these signs are so suggestive of serious injury that a conservative regimen must be followed.

Injuries to the abdominal viscera threaten not only the well being but the life of the injured athlete. Any abdominal trauma that causes more than momentary symptoms must be considered a life threatening injury, and demands conservative management. The "let's take a chance" philosophy, that might be permissible with less potentially lethal injuries, has no place in the management of abdominal trauma.

Neurological Conference

Herniated Intervertebral Disc*

Dr. Robert Soll:** The patient today is a 32-year-old housewife who first experienced difficulty with her back approximately one year ago. She and her husband had been in the process of remodeling their home, and this activity included carrying sheet rock. As a result the patient had been doing a fair amount of lifting. One day while reaching for an object on a high shelf with her right hand, she felt a sudden sharp "pulling" sensation which radiated down her right leg into her toes. This discomfort persisted without change and was present almost constantly. During the ensuing months the pain gradually became more severe, finally requiring hospitalization of the patient. She was placed in pelvic traction in the hospital for approximately two weeks; the traction being increased to 20 pounds without relieving the patient's discomfort. She was subsequently referred to the University Hospitals for further evaluation.

For the past seven or eight years the patient has had minor back trouble described as a mild backache primarily in the lumbar area of the spine. She has also had some aching in her neck which has been associated with a headache at times. On one occasion she was told that her right leg was one half inch shorter than her left; therefore, she was treated with a shoe lift which she has worn ever since. The patient herself has not been certain of any benefit received from this shoe lift.

The general physical examination was within normal limits except for a mild scoliosis of the lumbar spine, which had a convexity to the left, and was associated with a slight pelvic tilt. On neurological examination the cranial nerves were found intact. The deep tendon reflexes were equal bilaterally in the upper extremities and at the knees, but the right ankle jerk was absent. There was weakness of both dorsiflexion and plantar flexion of the right foot, and an area of hypesthesia was present over the lateral aspect of the right lower leg and dorsum of the right foot. Straight leg raising elicited pain in the posterior right thigh and buttocks; deep palpation of the posterior thigh and buttocks produced tenderness along the course of the right sciatic nerve.

*Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatric conferences are held the first and third Wednesdays of every month from 3:15 to 4:15 p.m. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Charles Branthaver, in Pediatrics, and Dr. Robert Soll, in Adult Neurology. This conference was held Thursday, February 18, 1965, at 4 p.m.

**Adult Neurology and Moderator, University of Minnesota Hospitals.

Dr. John Brantner:* One can easily guess from talking with the patient what the results would be on her Minnesota Multiphasic Test. She is a cheerful, happy person. The test is completely normal in every respect. There was no depression or anxiety and her hysteria is high. She has some physical complaints but not many, and she is optimistic about the future. As far as the low back pain scale is concerned, I have no idea what it means in patients after surgery. Because of this large hysterical component her scale was in the border-line range of normal. However, it is difficult to apply this result to a patient who has already had surgery.

Dr. Richard Magraw:** Could you explain to us what the low back pain scale is?

Dr. Brantner: This scale was developed in an experimental attempt on the Minnesota Multiphasic to differentiate between patients whose low back pain was due to disc pathology proven by surgery and those who had low back pain with no demonstrable pathological changes at the time of surgery. It is rarely interpreted by itself; but, added to other information, it supplies one additional piece of evidence for or against the hypothesis of an organic cause of low back pain. Sometimes one finds an "organic" low back pain scale along with a Multiphasic, suggesting hypochondriasis or a conversion reaction. This helps in those cases in which a basically hysterical or hypochondriacal person develops low back pain due to an organic cause.

Dr. Lyle French:† This lady had signs and symptoms of an intervertebral disc compressing *the fifth lumbar nerve* which is usually compressed by a disc located between the fourth lumbar and the fifth lumbar vertebrae. This was chiefly manifested by numbness and weakness of her right great toe with a diminished right Achilles reflex. If *the first sacral nerve* had been involved, the numbness would have been along the lateral aspect of the foot and calf and she wouldn't have had any weakness of her great toe. The small lesion that is demonstrated on the myelogram is located between the fourth lumbar and fifth lumbar vertebrae and thus fits with the physical findings. One has to be careful in localizing these lesions in order to determine accurately the proper site of operation; one should appreciate the fact that it is easy to be thrown off one cord level. This defect corresponds to the one that we found at the time of surgery.

Dr. Soll: I would like to emphasize also that the history can be of great importance in characterizing the type of herniation that exists. Commonly, back pain associated with disc disease is accentuated in the erect position and tends to be relieved by lying down. It must be kept in mind, however, that the reverse situation can paradoxically exist, that is, pain can be increased by lying down and can be relieved by getting up and walking. The explanation that is usually given for this phenomenon is that an extruded disc has compressed and fixed a nerve at one of the intervertebral foraminae. Upon lying down the weight of the body is removed from the spinal column and there is a tendency for a gradual lengthening of the column to occur as a result of an expansion of the intervertebral discs. Normally the spinal nerves can compensate for this stretching by freely moving within the intervertebral foraminae; however, if a spinal nerve has been fixed by an extruded disc, the nerve itself becomes stretched, thus eliciting pain which can be relieved by again arising and walking around until the spinal column gradually shortens. This paradoxical history should be remembered in those cases in which a disc is suspected. Dr. French, would you describe the operation which you performed on this patient?

---

*Assistant professor clinical psychology, University of Minnesota Hospitals.

**Director, Comprehensive Clinic Program, University of Minnesota Hospitals.

†Professor and director neurosurgery, University of Minnesota Hospitals.

Dr. French: We performed the usual operation for a herniated disc. In this situation the patient is lying prone. A six-inch vertical incision is made in the mid-line centered over the spinous processes overlying the region of the involved disc. The erector spinae muscles are separated from the spinous processes and from the laminae, thus exposing the ligamentum flavum. A hemilaminectomy is then performed in which a little bit of bone is removed from the laminae above and below the lesion. This actually leaves the laminae still intact and strong. We do not go out to the articular facet, as this would weaken the spine. Thus the dural sac is exposed and the nerve root comes into view laterally where it is being compressed by the protruding disc. The posterior longitudinal ligament is incised, and we then go down into the interspace and remove the cartilaginous disc tissue from within the center of the intervertebral disc as well as that part which has herniated. All the disc is not removed but rather approximately two thirds of the total disc tissue. This particular patient had a degenerative disc, but not a completely extruded, free-fragment type disc such as those encountered at times after a severe injury. Completely extruded discs often occur after falls from very high places, such as from a ladder. With these types of accidents a piece of disc may herniate which often can be as large as the tip of one's thumb. This patient did not have this type of disc; her disc was one which results from chronic degenerative changes. Acute symptoms are usually precipitated by a lesser injury which permits sudden disruption of the disc. Subsequently, the gradual wear and tear of ordinary life will make the disc degenerate more and more; thus it will progressively bulge out farther, increasing the symptoms with the passage of time. Twisting and turning movements are particularly apt to aggravate this type of disc degeneration and we advise patients to minimize such activity. An example of such activity is bowling, which requires bending and twisting movements of the back which should be avoided. After the disc is removed we simply suture the fascial layers together, closing the wound.

Dr. Magraw: Does the disc ever become very soft?

Dr. French: I don't believe there is ever any real liquefaction of the disc, although this term is used. The intervertebral disc will not dissolve; thus disability caused by it will not disappear; likewise it will not be resorbed or diminished. The lesion is fundamentally due to a break in the continuity of the posterior longitudinal ligament. Rotation of the spine produces a twist in the annulus fibrosus which is the outer part of the intervertebral disc enclosing the nucleus pulposus. As a result of this twist the nutrition to the nucleus pulposus, which is actually a remnant of the original notochord, is reduced. The nucleus pulposus then gradually degenerates and extrudes through a crack in the annulus fibrosus. Occasionally a degenerative disc may gradually extrude part way producing symptoms; manipulations of the back can sometimes work this disc back into its proper location, thus relieving the symptoms.

Dr. Magraw: Are there any microscopic changes in the disc itself?

Continued

Dr. French: Yes, there are microscopic changes. There are also chemical changes. The character of the nuclei in the nucleus pulposus itself is changed and the character of the chondroitin sulfuric acid is changed. The main point is that once one has an early disc, any further wear and tear of everyday life is going to make it worse. If one adds the aggravation of a quick twisting movement, a sudden fall, or overweight, the condition will become much worse.

Student doctor: What happens to the intervertebral space once the disc has been removed?

Dr. French: The vertebrae simply settle together. Actually they probably have already settled together somewhat because the disc tissue has partially extruded. Fibrosis gradually occurs in the area from which the disc tissue has been removed and, in some respects, the area probably becomes even stronger eventually than it was prior to the illness.

Student doctor: What are Williams' exercises?

Dr. French: Williams' exercises are a series of exercises to strengthen the back muscles. Frankly, I feel that Williams' exercises are to some extent good but also in other respects bad for degenerative disc disease. Those exercises that include raising and lowering the legs when one is lying down to help increase the tone of the back and abdominal muscles are good. In the shower, movements such as stretching and raising the arms above the head also allow gentle exercise of the muscles and help to increase their strength and tone. Other exercises, however, such as violent twists or turns and touching the toes, produce a lot of extra stress on the back, only aggravating degenerative changes.

Student doctor: Will traction improve a herniated lumbar disc?

Dr. French: Usually pelvic traction for a herniated lumbar disc does no good other than to keep a patient in bed. If there are symptoms of a cervical herniated disc, traction may tend to relieve the patient; but I feel that the idea of trying to pull out the strongest muscles on an individual's body like the back musculature by traction on the legs or hips is not feasible. It would be better simply to keep a patient in bed in a somewhat flexed position; such a position puts less stress and strain on the muscles of the back, thus reducing the muscle spasm and occasionally relieving the pain. At times manipulations of the back similar to chiropractic manipulations may cause symptoms abruptly to disappear.

Dr. Magraw: What proportion of patients pick up their bed and walk after disc surgery

Dr. French: I think this varies greatly, depending on the character of the disc and also on the type of person who is having the operation. In an industrial case in which a man would earn $42.50 if he didn't work, and $44.50 if he did, it would be difficult to get him right back on the job; this would be especially true if he were 54 years of age, had been doing hard labor all of his life and was getting tired of it. If one selects only individuals who have a good clear-cut disc syndrome, who are energetic and depending on steady employment to make a living, they will not only go back to work before two months, which is the usual time for an industrial case to return, but they will usually recover within two to four weeks time. I don't believe I have ever operated on truly private entrepreneurs with no income unless they worked, who didn't return to work within two or three weeks. There are also many other people who fit into this category. A classic example in my own experience was a navy pilot who had three years to go before his retirement. At that time he couldn't walk or sit because of symptoms of a herniated lumbar disc. If he had been retired because of disability, his retirement pay from the navy would have been very low. He entered the hospital on a Friday night; I operated on him the next morning; and he returned to work the following Monday morning. No one in his outfit even knew that he was ill. I think that if we took all farmers and operated on them, 90% of them would go back to work soon. If we took all industrial cases, including work such as carrying a quarter of beef, driving a truck across the country or lifting sacks of potatoes, 50% would soon return to work. If we considered a group of people in the 50 to 55 year age group who have been working for someone, they would remain out of work for two, three or four months and then gradually return to their jobs. Altogether 70 to 75% of these patients will eventually return to full time work. There is this variation.

Student doctor: What activities do you instruct patients to avoid?

Dr. French: I tell them to avoid lifting very heavy weights and any violent twisting movements; I also tell them specifically to quit bowling. Bowling is a very poor sport for people with back trouble. I also feel that a patient should not drive a car long distances without stopping periodically every hundred miles or so to get out and stretch. This type of strain wouldn't actually cause a recurrence of a disc but it does stiffen back muscles, thus causing low back pain due to muscle spasm.

Dr. Soll: Is there a specific indication for an anterior approach to a herniated disc?

Dr. French: Yes, I don't believe anybody does an anterior approach to the ordinary herniated intervertebral disc. Anterior approaches are done when a secondary fusion of the vertebrae is planned. Such a fusion would be indicated in people who have had a number of operations for discs and not been relieved of pain. The hope is that this type of fusion will alleviate some of the symptomatology. Posterior fusions have been shown not to be of much benefit as far as fixation of the spine is concerned. There are several reasons for poor results after removal of an intervertebral disc: first, a patient may not have a herniated disc at all but rather some other lesion, such as a spinal cord tumor, spondylolisthesis,* or an anxiety state in which the complaint is "oh, my aching back;" second, the surgeon may not do an entirely neat job as far as the excision of the disc tissue is concerned; for example, the nerve roots may be traumatized, the dura may be torn, there may be too much bleeding in the operative area, or all the disc tissue may not be found. At times this tissue may extrude far laterally and may not be discovered unless looked for specifically. I am discussing all the things that could happen; I don't mean to imply that all these things necessarily do happen. Finally, a patient may have just reached that time in his life when he has lost the desire to continue working. This last possibility may be the result of aging, dislike for the boss, or a feeling that his wife should start working instead of just lying around. There are a lot of reasons for which one could get poor results.

THE PATIENT ENTERS THE ROOM FOR QUESTIONING

Dr. Soll: (to the patient) Would you tell us what your pain was like initially?

---

*See Test Your Word Score Page 1491.

Continued

Patient: When I first got the pain, it was like a line going up my leg to my hip. It was quite sharp. The pain later just grew from there and became a throbbing in my ankle, knee, and hip. I didn't have any real backache to speak of until just lately. Recently I have noticed a stiffness in my spine. Of course, I did have a lot of pain when I was in traction last fall.

Dr. Soll: Was it worse in traction than when traction was not applied?

Patient: Not especially, but I did feel tingling in my toes when I was in traction. First it was in my little toes but later the big toe was affected also. Just having a sheet over my foot was painful.

Dr. Soll: Was the pain any worse when lying down in contrast to being up and about?

Patient: If I could be up for about an hour and then stay up it would be better, otherwise it would be better when I was lying down.

Dr. Soll: Did you ever have to get up at night to walk it off?

Patient: No, that would do no good unless I could be up at least an hour.

Dr. Soll: Has the pain changed any since the operation?

Patient: Oh, yes, I can sit now and it doesn't bother me.

Dr. Soll: Is there any discomfort at all?

Patient: No, there is just stiffness in my back. Of course the tingling in my toes is still there, but I guess that will improve.

Student doctor: As a child or young lady, were you ever conscious of any pain in your leg or back, or was there any indication that there was something wrong?

Patient: No, not to my knowledge. My mother looked for signs afterward and she noticed that I wore out the sole of my right shoe more. Whether this is significant or not, I don't know.

Dr. Magraw: How close are you to becoming completely well?

Patient: Very close, I hope.

Dr. Magraw: What do you mean, you hope?

Patient: Once the stiffness has gone away I should be well except for taking it easy. I have all my reflexes back. It is good to see them all jump again.

The Patient Exits the Room

Miss **Helen Kretchmer:**[*] There are three small children in the family — aged three, nine and 15. The family lives on a farm which they have been purchasing over a period of time. It is a very modest farm in an area which will become part of the state game reserve. Although the state will probably buy their farm, they will still be able to live on it. In the past they have lived in various parts of the country. The husband built the house they are now living in with his own hands, and I presume that the patient helped a great deal. At the present time the family is cared for by the husband, who takes the smallest child to a babysitter during the day while the other children are in school. When the patient goes home she may need some assistance with heavy work for a while. She has a very well organized family; otherwise they would need a homemaker. The family has only a marginal income. The father's income is fairly modest, about $292.00 per month as a hardware salesman. They are gradually paying for their farm, and any great added expense would be difficult for them. Their hospital bill is already $400.00. In addition to their farm and the father's wages they own a small property in another state which that state wants to buy. This could be liquidated to provide money for them now.

Religion Circa 90 A.D.

The following letter written by Pliny is esteemed as a record of ecclesiastical antiquity, written about 40 years after the death of St. Paul.

To the Emperor Trajan:

It is my invariable rule, sir, to refer to you in all matters where I feel doubtful — having never been present at any trials concerning those who profess Christianity, I am unacquainted not only with the nature of their crimes, — but how far it is proper to enter into an examination concerning them. Whether repentence entitles them to a pardon; or if a man has been once a Christian, it avails nothing to desist from his error; whether the very profession of Christianity, unattended with any criminal act, or only the crimes themselves inherent in the profession are punishable; on all these points I am in great doubt. I asked them whether they were Christians; if they admitted it — if they persisted I ordered them to be at once punished: for I was persuaded, whatever the nature of their opinions might be a contumacious and inflexible obstinacy certainly deserved correction — some among those who were accused by a witness in person at first confessed themselves Christians, but immediately after denied it. They all worship your statue and the images of the gods, uttering imprecations* at the same time against the name of Christ. They affirmed the whole of their guilt was that they met honestly today and addressed a prayer to Christ, as to a divinity, binding themselves by a solemn oath, not for the purpose of any wicked design but never to commit any fraud, theft, or adultery, never to falsify their word or deny a trust when they should be called upon to deliver it up. From this custom they desisted after the publication of my edict by which according to your commands I forbade the meeting of any assemblies — all I could discover was evidence of an absurd and extravagant superstition. In fact this contagious superstition is not confined to the cities alone, but has spread its infection among the neighboring villages and country. Nevertheless, it still seems possible to restrain its progress.

Trajan to Pliny:

You have adopted the right course, my dearest secundus — against the Christians who were brought before you. If indeed the crime (of Christianity) is proved they must be punished with the restriction, however, that while the party denies he is a Christian and shall make it evident that he is not, by invoking our gods, let him, not withstanding any former suspicions, be pardoned upon his repentence. Anonymous information ought not to be received in any sort of prosecution. It is introducing a very dangerous precedent and is quite foreign to the spirit of our age.

Child Psychiatry

School Failure*

"School failure?" the physician may ask, "What has that to do with me?" The answer is, of course, "Quite a lot if you deal with children and their parents."

Contrary to the expectations of most parents, a significant number of children do fail in school. Whether the child fails academically or whether he fails to make the necessary behavioral adjustment, he is threatened in three ways: (1) He recognizes his own inability to compete successfully; (2) he senses the disappointment of his parents; (3) he loses the acceptance of his peers. Persistent failure builds up the child's concern to the point where his tolerance capacity is exceeded and he seeks a way out. One comfortable way out — because it is acceptable — is illness or the manifestation of symptoms of illness. This is where the discerning physician comes in.

School failures are costly, not only to the individual but to society. The physician has a responsibility to the child, the parents, the school, and the community to recognize danger signals and to apply or recommend preventive measures. If serious failure has already occurred before the physician is consulted, he must ferret out the underlying causes, deal with those within his purview, and enlist the help of other experts when necessary.

Indications of Impending Trouble

The most frequently encountered indications of impending trouble are: (1) an abrupt change of pace in general behavior — increased restlessness, inability to apply self to an assigned task, excessive day dreaming, deterioration in interpersonal relationships; (2) a marked reversal in attitude and disposition — unexplained fearfulness, a tendency to be easily upset, withdrawal from group activity, lack of the usual enjoyment of companionship; (3) a sudden drop in academic performance; (4) persistent offering of physical complaints — headache, stomach ache, fatigue, and the like; (5) exaggeration of or increase in the frequency of asthmatic attacks or convulsive seizures, difficulty in diabetic control; (6) repeated absences from school because of illness; (7) a developing pattern of tardiness and/or truancy; (8) out-and-out refusal to go to school where the child's helplessness is manifested by his saying, "I *can't* go to school," rather than "I *won't*."

The underlying causes of school failure tend to fall into five general categories. They may be present in varying combinations, depending on the child's age and the circumstances of his life. Sometimes the root of his difficulty can be readily diagnosed, but other factors feed the root. The total problem is likely to be complex.

---

*In the hope of stimulating further interest in the art of dealing with children and their parents, the editor has agreed to publish a series of papers on subjects of special relevance.

Continued

Academic Potential

Adequate academic potential is essential for school success. When a child is failing, his mental ability obviously should be evaluated. While the services of a competent psychologist are invaluable in measuring the intelligence factor and analyzing its impact, a physician alert to the significance and meaning of developmental norms for any given age group usually can at least estimate the child's general capacity.

Intellectual Level

In terms of academic potential, children can be classified as gifted, superior, average, borderline, and retarded. School failure can occur in any of these groups, though children of average capacity usually fail for other reasons. Marked retardation is easy to spot, but the group falling between the obviously retarded and those classed as "average" is more difficult to define. In general, these borderline children tend to have trouble from the beginning, hovering between passing and failing until the fourth or fifth grade. At this point failure is the rule. Because they are capable of competing successfully with their peer group in all areas of activity except "book learning," their limitation in this respect may have been overlooked. All too often parents and teachers mistakenly expect too much of them. Their inability to live up to such expectations adds another stressful dimension to their failure. The first requirement in cases like this is clarification and acceptance of the reason for unsatisfactory academic performance. The next is a modified program which utilizes their manual skills and enables them to attain reasonable pleasure and satisfaction from school work. Continuing to pass them along in the usual fashion without regard for their limitations only magnifies their frustration and resentment.

Boredom

The superior or gifted child may fail because he does not have sufficient opportunity to utilize his full potential. The curriculum in most school systems is designed for the average child. Early in his school experience the above-average child may get bored. As his boredom and consequent resentments mount, he may become an "acting out" problem. Relieved of the necessity to really apply himself, he may develop poor study habits. Then as he advances and assignments become more difficult, his poor habits take their toll and his achievement is not commensurate with his ability. On the other hand, a different kind of problem may result from advancing the superior or gifted child a grade or two without considering whether he is physically, socially and emotionally mature enough to compete with older children. To avoid complications, the child's capacities to deal successfully with the total range of competition must be assessed, and the child himself should participate in the decision. How he feels about the changes involved in advancement is important.

Experimentation with the ungraded approach, particularly at the elementary level, is an encouraging development. As more schools adopt it, many of the problems related to variations in academic potential may be eliminated.

Physical Disorders

Physical defects may be responsible for school failure. Accurate perception is a first essential in the learning process. Any defect of sight or hearing penalizes the child. Minimal defects are more, rather than less, important, because they are likely to be overlooked. The result is accumulated strain which saps the child's vitality. Early recognition and correction of the defect may avert failure. The child handicapped by poor muscular coordination, and control needs special consideration and encouragement. Speech disorders such as stammering or those related to cleft palate defects likewise may contribute to school maladjustment.

Chronic and acute illnesses take their toll in school failure. Repeated or prolonged absences from school cause the child to get behind in his work and everything looks hopeless. Part-time tutoring during convalescence often is the answer. If a child exhibits general disinterest and lassitude, the possibility of malnutrition with an associated anemia must be considered. Unusual physical features such as tallness or shortness, obesity, or a physical deformity may be indirectly responsible for school failure. Through discussion and reassurance the physician may be able to help the child accept his difference.

Special Disabilities

An obvious prerequisite for successful performance in school is the ability to read satisfactorily, yet estimates suggest that 10-20 per cent of our children are unable to do so. Modern methods of teaching reading account for some of this difficulty. Children who do not respond to the "flash card" system may require intensive work in old-fashioned phonetics. A small, but significant, group have a specific reading and writing disability. These children as a rule are late in establishing — or may never establish — cerebral dominance. They tend to reverse words and letters. For example, they see "saw" for "was" and vice versa, or confuse "b" and "d," "p" and "q." Some are mirror writers and readers, seeing "yod" for "boy." Children of this type encounter trouble in the early grades, and their ability to compete diminishes progressively, though they may do well in subjects which do not require reading. They need intensive help from specially trained individuals.

Inadequate Preparation

Another group of children fail because of inadequate preparation in the fundamentals — reading, writing, spelling and arithmetic. Poor teaching may be responsible, but more often the key to their dilemma lies in a history of changing schools. It is estimated that approximately one third of our population is mobile. Adjustments to varying academic standards, new teachers and different methods, new classmates, and new surroundings are not easy — particularly for the young child. Still another group fails because of inadequate social preparation. A good example is:

Excessive Emotional and Nervous Tension

Emotional disturbances in children are not sufficiently recognized as causes of school failure. They are particularly important when the child begins his school career. From this time on, the responsibility for adjustment rests primarily with him. The attitudes of his teacher, his parents, and his doctor can either help or hinder the adjustment process. Real or imagined fears as well as anxiety — the commonest nervous disturbance

Continued

in both children and adults — may be instrumental in failure. The tactless and unsympathetic teacher, the nagging parent who expects too much of the child, parental discord, or the lack of full acceptance on the part of anyone important to the child can create anxiety. Fear of failure, punishment, criticism, or heckling by fellow students may produce sufficient strain to cause failure. In adolescence tensions may increase with problems centering around emancipation from the home, choosing a life's work, and developing heterosexuality. Wise guidance in these areas may mean the difference between school failure and success. The physician is in a strategic position to offer such guidance, provided he understands and remembers that children need support and encouragement in their struggle to adjust themselves to life as they find it.

Summary

The early diagnosis and management of school failure effects a total saving to the child, the home, the school, and the community. In this the physician can be helpful. Careful search will usually reveal the reason for failure. When this has been determined, a plan of treatment designed to meet the needs of the child can be arranged. For the more complicated cases, referral for specialized help may be desirable. An objective, but sympathetic, interpretation of the child's needs to the parents as well as to the school will do much to reduce the likelihood of school failure and to improve the general health of the school child.

The Tobacco Tyrant*

Favagoer noted arrhythmia, bradycardia and tachycardia, precordial pain, dyspnea, cardiac asthma, cyanosis, and even Cheyne-Stokes respiration. He reports a fatal case of "Cardiac Paralysis" in which autopsy showed dilatation and fatty degeneration.

Potter's Materia Medica says: "Nicotine is almost as rapidly fatal as Prussic Acid, death having occurred from a toxic dose in three minutes, with no symptoms except a wild stare and a deep sigh. The continued use of tobacco in excess by smoking or chewing produces granular inflammation of the fauces, and pharynx, atrophy of the retina, dyspepsia, lowered sexual power, nervous depression, and occasionally angina pectoris. Used by the young, it hinders the development of the higher nerve centers, and impairs the body nutrition by interfering with the process of digestion and assimilation."

Rolleston says that he has seen two severe cases of anginoid pains, such as substernal oppression and tightness on exertion, and that this is not uncommon in smokers.

Kjelberg believes in a specific psychosis from tobacco. Ziehen and Obersteiner speak of tobacco paralysis.

Clinical Path Conference

Pathology of Sudden Death*

When a physician is called upon to minister to a person who has "just died" or one who has suddenly developed a state of extremis, planning and execution of resuscitative measures must be pertinent to the condition at hand. Under the dramatic circumstances considered, an exact diagnosis of the basic problem cannot always be made; but it is helpful for the physician to have an awareness of the potential of the problems with which he is faced. Such an awareness may be derived from knowledge of the conditions which may cause sudden death. It is the purpose of this report to review these conditions.

Sudden death, as used in this presentation, is defined as a nontraumatic phenomenon in which, following a stable state, the subject either instantaneously or after a brief episode of discomfort loses all vital functions. Sudden death results from failure of the (1) nervous, (2) respiratory or (3) circulatory system from a variety of causes and mechanisms (Table 1).

Continued

I-Nervous System

Only rarely do acute lesions of the central nervous system cause sudden death, as in most instances, regardless of how extensive the lesion, the subject maintains circulatory and respiratory functions for several hours at least. In a rare instance of infratentorial hemorrhage, such as rupture of an aneurysm of the circle of Willis, will death from a lesion of the nervous system be sudden.

II-Respiratory System

Respiratory disturbances that cause sudden death are usually those resulting from lodgement of a foreign body in the major airway. Included in this category is the phenomenon in adults of aspiration of a large bolus of food such as a piece of inadequately chewed meat. In children, respiratory failure that leads to sudden death is at times identified as resulting from aspiration of a foreign body. The so-called "crib death," a circumstance in which a seemingly healthy infant is found dead, may result from one of many causes. Recognized respiratory lesions include pneumonia and bronchitis, but in many of such subjects no significant lesion is demonstrable.

In adults respiratory failure may result from aspiration of blood from rupture of a major arterial vessel into the airways. Included among underlying lesions are (1) aneurysm of the thoracic aorta, (2) postradiation necrosis of a carotid artery and (3) mycotic aneurysm of a pulmonary artery.

III-Circulatory System

Collectively, circulation disturbances constitute the most common cause

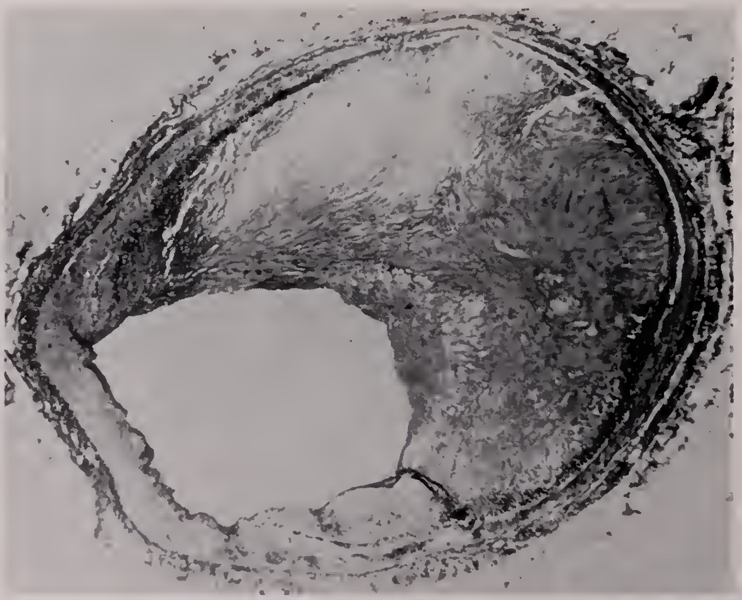

Fig. 1 — Photomicrograph of a coronary artery showing the typical lesion of atherosclerosis. This lesion represents the underlying factor in the majority of cases of sudden death among the population of this country. Elastic tissue stain; x40.

for sudden death. These may be subdivided into four major groups as follows: (1) myocardial failure, (2) cardiac compression, (3) hemorrhage and (4) circulatory obstruction.

Myocardial Failure

Myocardial failure may be subdivided into that resulting from (1) an arrhythmia and (2) sudden strain upon the left ventricle.

Fatal Arrhythmia

An arrhythmia which distorts the circulatory system to the degree that it causes sudden death takes the form either of ventricular fibrillation or cardiac standstill. These two arrhythmias collectively may be called fatal arrhythmias and constitute the most common cause of sudden death.

(a). Coronary Atherosclerosis

Among the many background diseases responsible for a fatal arrhythmia, coronary atherosclerosis stands out as the most prevalent (Figure 1). In the study of Spiekerman and others in Rochester, Minnesota, with which the author was associated,[1] the incidence and types of coronary deaths among residents of that community were determined. Representing a necropsy percentage of about 67 of all deaths occurring in and out of hospitals over a six-year period, the study included 691 necropsies of subjects 20 years of age or older. In this group there were 221 deaths attributable, in one way or another, to coronary atherosclerosis. This represented 41 per cent of the 373 males and 22 per cent of the 318 females in the study. Significant was the fact that the most common single type of death (as determined from history and necropsy findings) was sudden death considered to have resulted from a fatal arrhythmia without acute myocardial infarction. This factor was regarded as operative in 94 subjects, constituting 43 per cent of all coronary deaths. This figure was slightly

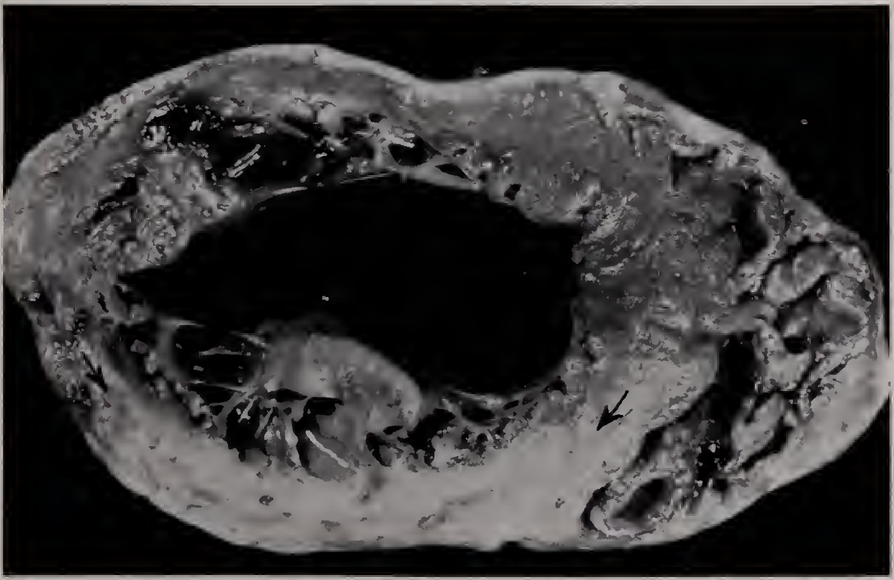

Fig. 2 — Cross section of ventricles of the heart in an instance of healed anterior and acute posterior (between arrows) myocardial infarction. In instances of acute myocardial infarction sudden death is often the result of acute changes in the function of the viable muscle around the infarct rather than changes in the infarct itself.

Continued

higher than the incidence of death associated with acute myocardial infarction which occurred in 87 subjects or 39 per cent of the coronary deaths. Moreover, the high incidence of an arrhythmia leading to sudden death among coronary fatalities was enhanced by the fact that in 20 of the 87 subjects dying with acute myocardial infarction the mechanism of death appeared to be the development of a fatal arrhythmia (Figure 2). Combining the 94 cases of sudden death without acute myocardial infarction and the 20 cases of sudden death with acute myocardial infarction there resulted 114 cases among the 221 coronary deaths in which a coronary death appeared to have resulted from an arrhythmia.

From Tables 2 and 3 it is evident that the majority of subjects dying suddenly of coronary disease are (1) out of hospital and (2) do not suffer from acute myocardial infarction. Scars of healed myocardial infarction are common among such subjects.

TABLE 2
Myocardial Changes in 114 Instances of Sudden Death of Coronary Origin. Modified from Spiekerman and Associates[1]

Condition	Per cent
Normal Myocardium	12
Healed Infarction	70
(Gross)	(42)
(Patchy)	(28)
Acute Infarction	9
Acute and Healed Infarction	9
Total	100

TABLE 3
Location of 114 Subjects Dying Suddenly from Coronary Arterial Disease. Modified from Spiekerman and Associates[1]

Place	Number of Cases	Per cent
Home	77 (65 slight to moderate activity; 12 asleep)	67
In public place	10	9
At work	9	8
In hospital	18	16
Total	114	100

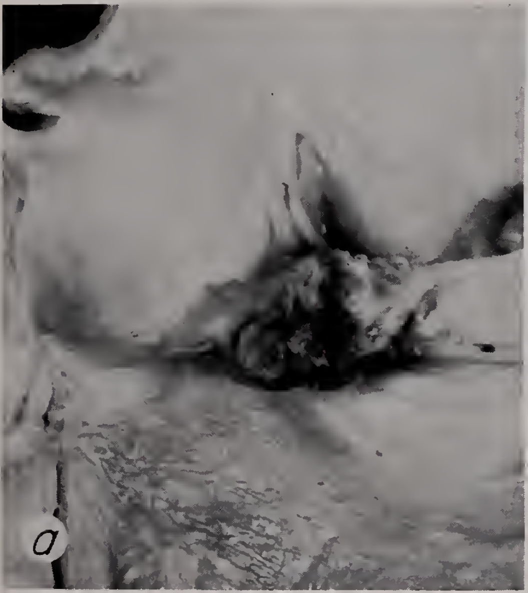
It is of further interest to review the causes of death among patients with scars of healed myocardial infarcts, as these represent examples of patients who had recovered from acute myocardial infarction. The combined studies of Achor and associates[2] and of Juergens and associates[3] yield 329 cases of necropsy-proved healed myocardial infarction. Two thirds of these subjects died of causes related to the coronary arteries.

These causes could be grouped into three categories as follows: (1) sudden death, (2) circumstances related to recurrent acute myocardial infarction and (3) congestive cardiac failure. Of these three groups sudden death was the largest, being represented by 38 per cent of the subjects with healed myocardial infarction who died of coronary disease. In the combined studies to which reference was made, recurrent acute myocardial infarction was observed in 34.5 per cent of coronary deaths and congestive cardiac failure in 27.5 per cent.

A relatively unusual type of acute coronary insufficiency is that resulting from coronary embolism. Sources for such a process included bacterial endocarditis (Figure 3), particles from a calcified aortic valve, left atrial myxoma, mural thrombi of the left atrium or ventricle, and bronchogenic carcinoma that has invaded a pulmonary vein.

(b). Left Ventricular Hypertrophy

It may be taken as axiomatic that the hypertrophied left ventricle (Figure 4) represents a hazard (including the possibility of sudden death)



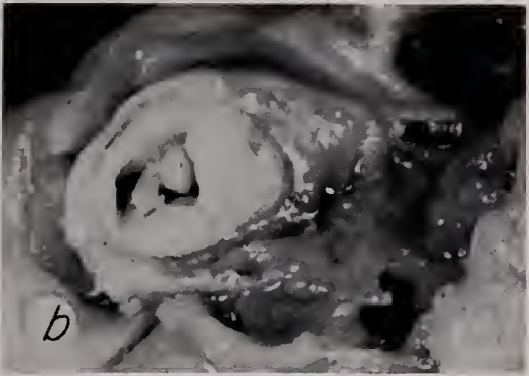


Fig. 3 — Bacterial endocarditis and coronary embolism in a 49-year-old man who died suddenly. *(a)* Segment of the aortic valve in which two leaflets are interadherent. At the zone of adhesion a vegetation of bacterial endocarditis is present. *(b)* Cross-section of the anterior descending coronary artery showing an embolus occluding the lumen, a process considered to have been the basis for sudden death.

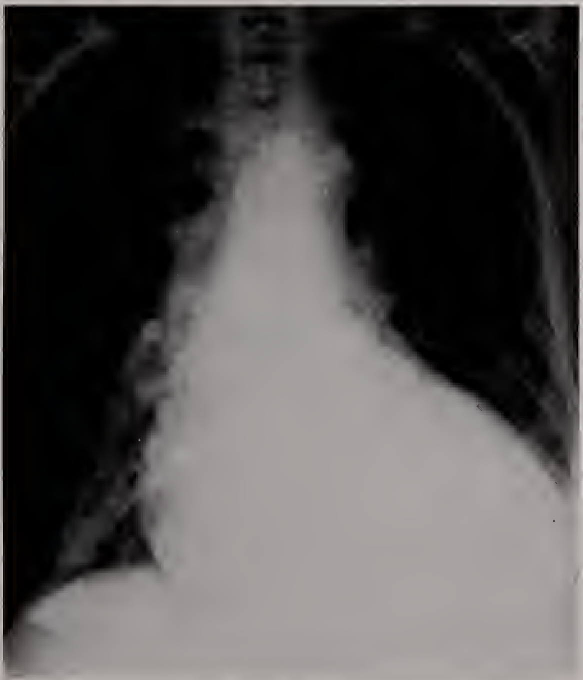

Fig. 4 — Roentgenogram of thorax of a patient with aortic valvular disease showing features of left ventricular enlargement. The left ventricular enlargement, of itself, may be a basis for sudden death.

Continued

to the patient, regardless of the cause of the hypertrophy. In the majority of cases the basis for the left ventricular hypertrophy is evident, frequently taking the form of aortic valvular disease. In other instances one observes examples of sudden death with left ventricular hypertrophy after the basis for the left ventricular hypertrophy, such as coarctation of the aorta, aortic valvular disease or patent ductus arteriosus, has been surgically corrected. The cause of sudden death in instances of left ventricular hypertrophy may perhaps be related to myocardial ischemia resulting from the hypertrophied muscle causing an inordinately high degree of resistance to capillary flow.

Obstruction to left ventricular outflow constitutes a particularly common cause of left ventricular hypertrophy and of sudden death. Special consideration needs to be given to this subject.

(c). Left Ventricular Outflow Obstruction; Aortic Insufficiency

Three anatomic states are responsible for obstruction to left ventricular outflow (Figure 5). In order of decreasing frequency these are (1) aortic stenosis, (2) subaortic stenosis and (3) stenosis of the ascending aorta (supravalvular aortic stenosis). As the subjects of aortic valvular stenosis and aortic insufficiency are each closely related to the subject of sudden death, these will be considered together.

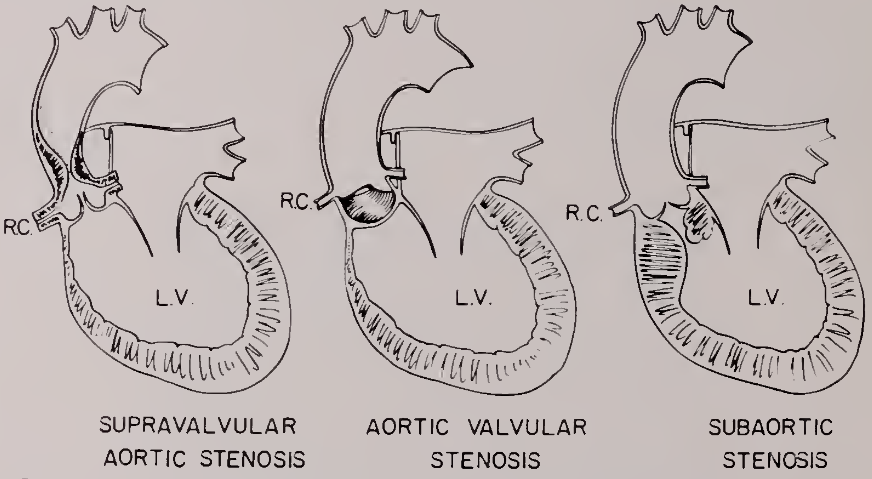

Fig. 5 — Types of obstruction to left ventricular outflow in relation to the aortic valve. These are supravalvular aortic stenosis, aortic valvular stenosis and subaortic stenosis. Each of these types may be associated with sudden death. Illustration from Edwards.[11] Reproduced with permission from the American Heart Association.

Among patients dying with aortic valvular disease, whether the disease takes the form of stenosis or of insufficiency, sudden death is common (Figure 6). In a series of 36 inhospital nonsurgical adult patients dying with aortic valvular disease, Nakib and associates[4] found that sudden death had occurred in 12 of the cases (33 per cent).

In some of these subjects coronary atherosclerosis was present to the degree that is commonly found among individuals dying suddenly of coronary disease without aortic valvular disease. In such subjects it is impossible to determine whether the aortic valvular disease or the coronary atherosclerosis was at fault. Nevertheless, in some of the subjects of Nakib, as in cases of other series in which sudden death was associated with aortic valvular disease, coronary atherosclerosis was present to only a mild and nonsignificant degree.

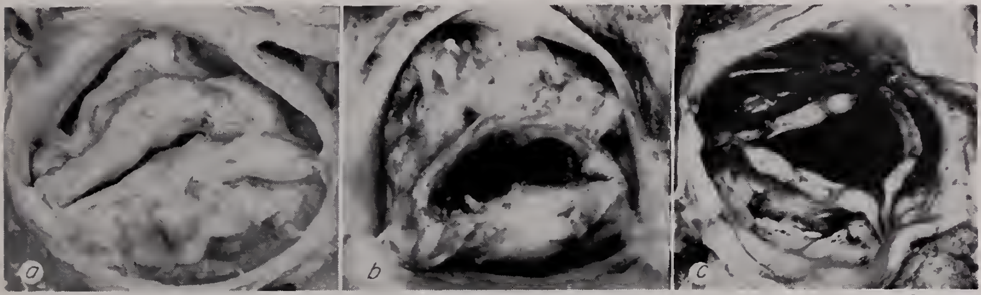

Fig. 6 — Types of aortic valvular disease which may be responsible for sudden death. *(a)* A congenital bicuspid aortic valve with acquired calcification yielding a stenotic valve. From a 65-year-old woman. *(b)* In a 43-year-old woman, a congenital bicuspid aortic valve which is calcified and stenotic. Coexistent retraction of the cusps causes the valve also to be incompetent. *(c)* Rheumatic aortic valvular insufficiency from a 25-year-old woman who died suddenly. Characteristic thickening and retraction of aortic leaflets leaving an incompletely guarded orifice.

The sudden death that results from aortic valvular disease is probably to be attributed to an arrhythmia associated with ischemia. Uncertain, however, is whether the ischemia is a direct result of the peculiar hemodynamic changes of aortic valvular disease or whether it is a result of the nonspecific problem of the associated left ventricular hypertrophy.

Special mention should be made of the problem of congenital aortic valvular stenosis. It is recognized that in infants or children with symptomatic aortic stenosis sudden death is commonly observed.

The other two types of obstruction to left ventricular outflow are subaortic stenosis and supravalvular aortic stenosis. With either of these conditions the patient may live to adult life but the danger of sudden death is ever present. In supravalvular aortic stenosis the tendency for premature development of coronary arterial obstructive lesions[5] may be an additional factor predisposing to sudden death.

(d). Complete Heart Block

Complete heart block in which Adams-Stokes attacks are classically associated has a strong tendency to cause sudden death, either through the development of ventricular fibrillation or cardiac standstill. In some patients the basis for complete heart block is clearly identifiiable, while in others its cause remains obscure. Identifiable causes include (1) surgical injury to the bundle of His during closure of a ventricular septal defect (Figure 7) or placement of a prosthetic aortic valve, (2) infiltration of the bundle of His by tumor, amyloid or inflammatory exudate, (3) congenital discontinuity of the major conduction pathways or (4) infarction of the bundle of His.

Heart block developing spontaneously in subjects over 60 years of age frequently is without a clear-cut anatomic basis. Moreover, the tendency for this disturbance to exhibit periodic variation in degree supports the view that continuity of the conduction tissue is maintained and that the problem is one of varying degrees of resistance to conduction, perhaps from ischemic or biochemical causes.

(e). Acute Myocarditis

Acute myocarditis may become complicated by sudden death. In some

Continued

subjects one may demonstrate necrosis and an inflammatory reaction in the bundle of His and clinically complete heart block may have been identified. In other subjects no major lesion of the conduction tissue is identifiable while ventricular extrasystolic beats may have been identified. Such beats may perhaps be taken as evidence for hyper-irritability of the myocardium and one may then infer further that this tendency may set the stage for ventricular fibrillation.

Sudden Strain Upon Left Ventricle

Sudden death may follow a state in which an acute load is placed upon the left ventricle. Under this category are two groups of conditions: (1) an acutely developing shunt and (2) acute valvular insufficiency.

(a). Acutely Developing Shunt

Shunts that develop acutely may be entirely or partially intracardiac or they may be extracardiac. For any given type some patients maintain sufficient cardiovascular efficiency to sustain life for weeks, months or even longer. In other subjects the same anatomic state results in death within minutes after its development.

The major completely intracardiac shunt is rupture of the ventricular septum occurring as a complication of acute myocardial infarction, usually in a posterior location.[6,7] In those patients who deteriorate dramatically from the newly developed interventricular communication, pulmonary edema and death occur rapidly in that order.

The classical partially intracardiac shunt which develops acutely is rupture of an aneurysm of an aortic sinus into a right-sided cardiac

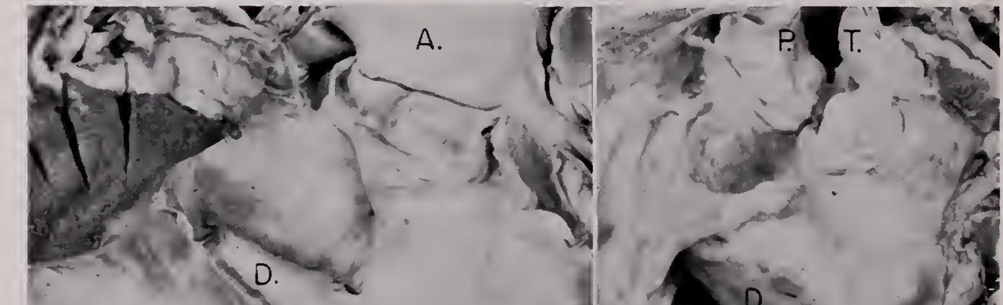

Fig. 7 — Specimen of heart from a 23-year-old man who developed complete heart block from closure of a ventricular septal defect. Sudden death occurred two months postoperatively. *(a)* Left ventricular (L. V.) aspect and ascending aorta (A.). Beneath the aortic valve is the site of the closed ventricular septal defect (D.). *(b)* Right ventricle (R. V.) and pulmonary trunk (P. T.). The site of closure of the ventricular septal defect with a prosthetic patch (D.) is evident. The prosthetic patch is, in part, encased by fibrous tissue.

chamber (Figure 8). Most commonly, the aneurysm is of the congenital variety and is not associated with evidence of cardiovascular disease until the dramatic event of rupture of the aneurysm. In a lesser number of cases the aortic aneurysm is of the mycotic type, being a complication of bacterial endocarditis.

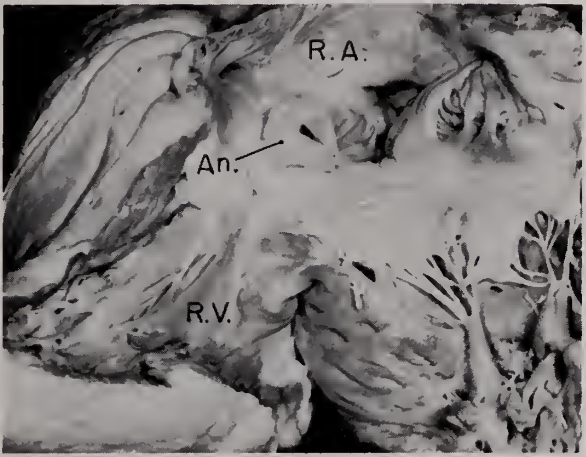

Fig. 8 — Rupture of an aortic sinus aneurysm into the right atrium. The aneurysm (An.) protrudes into the right atrium (R. A.) above the tricuspid valve. A laceration is present in the center of the aneurysm. R. V. = right ventricle. From a 45-year-old man who died suddenly.

The entirely extracardiac shunts that develop acutely are usually complications of syphilitic aortitis. In this circumstance either a uniformly dilated ascending aorta or a saccular aneurysm of the ascending aorta ruptures into an adjacent vessel such as the superior vena cava (Figure 9*a*) or a pulmonary artery (Figure 9*b*).

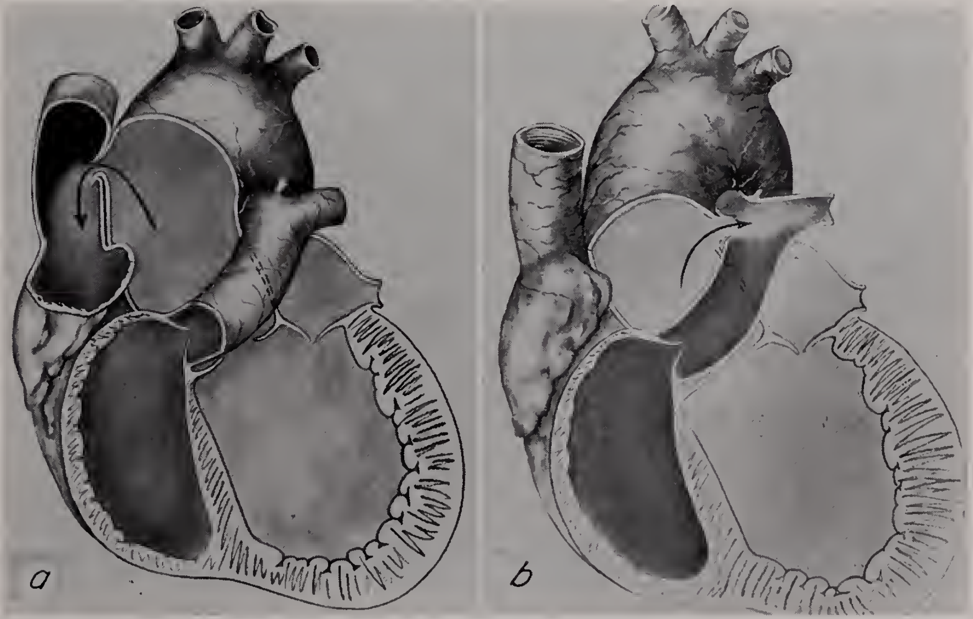

Fig. 9 — Diagrammatic portrayal of acquired shunts which may be responsible for sudden death. *(a)* Syphilitic aortitis with rupture of the aorta into the superior vena cava. *(b)* Syphilitic aortitis with rupture of the ascending aorta into the pulmonary arterial system.

Continued

As with ruptures of the ventricular septum or of an aortic sinus aneurysm, the appearance of an extracardiac shunt may be followed either by sudden death or by a state of sufficient cardiovascular stability as to maintain life for some time.

(b). Acutely Developing Valvular Insufficiency

As with acutely developing shunts the course of the individual patient with acutely developing valvular insufficiency may vary from a state of acute pulmonary edema and death within a few minutes to one of chronic cardiac decompensation.

When sudden death complicates acutely developing valvular insufficiency the valve involved is either the aortic or mitral.

Lesions of the mitral valve which pertain to the subject of this communication occupy two major categories as follows: (1) rupture of a papillary muscle complicating myocardial infarction or (2) rupture of chordae tendineae.

Rupture of a papillary muscle usually involves the posteromedial muscle of the left ventricle (Figure 10). The basic myocardial infarct is posterior or posterolateral in location.[8,9] In most instances of this least common type of rupture of the heart, the entire posteromedial papillary muscle loses its continuity. As a consequence, about half of the chordal support of the mitral valve is lost and the resulting mitral insufficiency is of gross proportion.

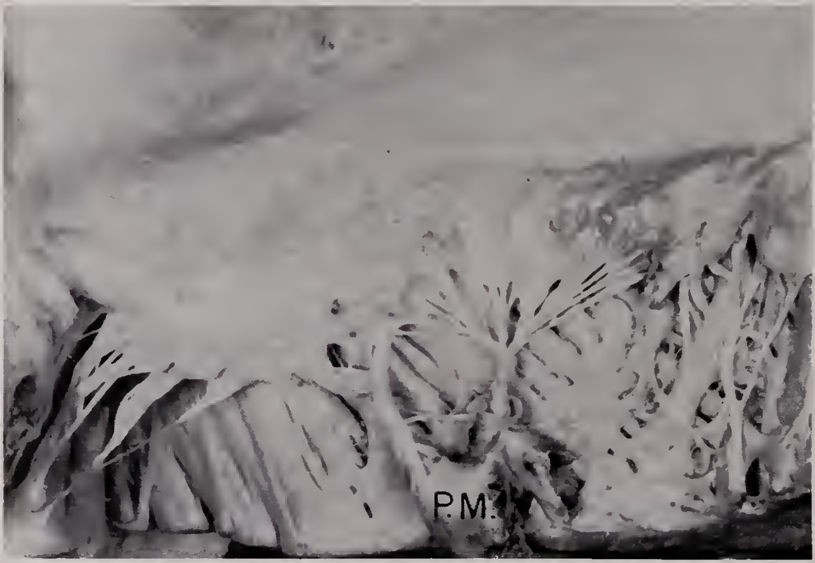

Fig. 10 — Rupture of the posterior papillary muscle (P. M.) in a man aged 53 years with acute myocardial infarction. Following rupture of the papillary muscle that part attached to the chordae had spun through a loop of the chordae to account for the twisted arrangements evident in the chordae. The loss of support of the mitral valve was responsible for acute massive mitral insufficiency.

Rupture of chordae tendineae, to be distinguished from rupture of a papillary muscle, may complicate bacterial endocarditis. More commonly, no underlying inflammatory process is identifiable.

Nontraumatic lesions which cause acute aortic valvular insufficiency primarily may involve either the aortic valve or the ascending aorta.

Within the sphere of the present discussion, primary lesions of the aortic valve are usually destructive complications of bacterial endocarditis. Lesions of the aorta which cause aortic valvular insufficiency involve a laceration of the aorta, as in dissecting aneurysm, a process which may cause either distortion of the aortic root or gross loss of support of part of the aortic valvular structure. In a rare case observed by the author an adult male patient exhibited a zone of avulsion from the aortic wall of the site of attachment of two aortic cusps (Figure 11). The basis for this peculiar nontraumatic avulsion is as yet not explained.

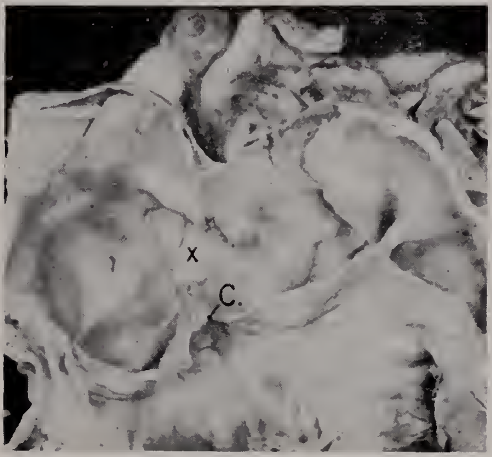

Fig. 11 — Aortic valve and a portion of ascending aorta in a 43-year-old man who died of hemopericardium from rupture of a dissecting aneurysm of the aorta. The commissure between the right and posterior aortic cusps (C.) had become avulsed from its attachment to the aortic wall as point x. Although this lesion had been present for some time before the dissecting aneurysm, it is conceivable that acute death could be caused from such sudden loss of aortic valvular support.

Cardiac Compression; Hemopericardium

Among the several varieties of pericardial disease causing cardiac compression (tamponade), hemopericardium is the one most likely to cause sudden death. Moreover, the accumulation of gross blood in the pericardial sac rarely allows the patient to survive for more than minutes. The great tendency for hemopericardium to cause sudden death stands in contrast to the consequence of an acutely developing valvular insufficiency or of a shunt. With the latter conditions, as has been suggested, while death may occur suddenly, many subjects survive for varying periods of time as examples of chronic cardiac disability.

There are two predominant causes of hemopericardium, namely myocardial infarction and rupture of the intrapericardial segment of the ascending aorta. Myocardial infarction which contributes to hemopericardium is always transmural in type. It occurs either through rupture of the free wall or by way of hemorrhage from associated pericarditis.

Rupture of the Heart

Rupture of the heart may be represented by rupture of a papillary muscle or by rupture of the ventricular septum, two lesions that have been considered in a foregoing section; but the most common type is that in which the rupture is through the free wall of the left ventricle, allowing left ventricular blood to escape into the pericardial sac. There are several features of rupture of the heart that are worthy of mention in addition to the fact that the type of infarct which becomes so complicated is transmural. There is a greater tendency for this complication to occur in women than in men. Of all patients dying with acute myocardial infarction rupture of the heart (usually of the free wall) occurs in about 15 per cent.

Continued

This figure is derived from the fact that of women dying with acute myocardial infarction about 30 per cent have suffered rupture of the heart, while in men dying of acute myocardial infarction about 8 per cent exhibit rupture of the heart. Rupture does not occur through scarred myocardial segments, and rupture of chronic cardiac aneurysms is essentially a nonexistent entity.

The tear itself tends to occur at the periphery of the infarct where paradoxical movement occurs during systole, the living muscle contracting while the infarcted muscle is stretched. After the primary laceration on this mechanical basis, blood dissects through the myocardium and epicardium and into the pericardial cavity (Figure 12).

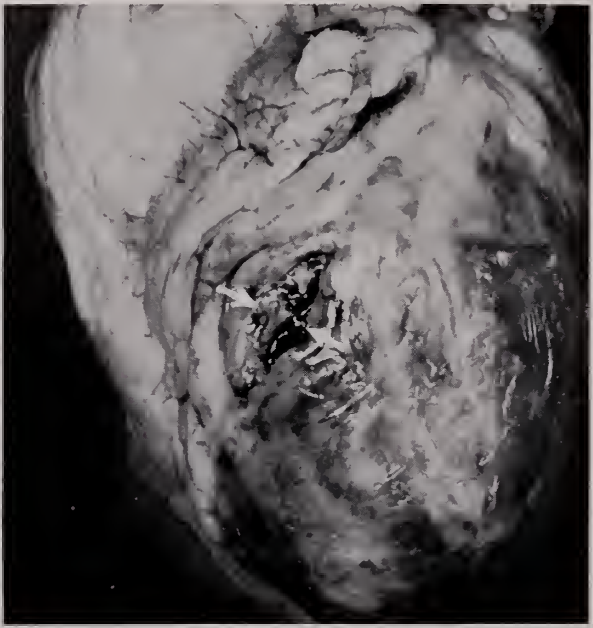

Fig. 12 — Exterior of anterior view of heart in a 65-year-old man with acute myocardial infarction. Rupture (between arrows) through the free wall of the left ventricle led to sudden death from acute cardiac tamponade.

In cases of transmural myocardial infarction *fibrinous pericarditis* may either overlie the zone of infarction or involve the pericardium diffusely. The vascular granulation tissue which participates in organizing the pericardial fibrin may bleed into the pericardial sac, the bleeding varying in amount and in rate of development. In extreme cases signs of acute cardiac tamponade may develop and result in sudden death. It is probably true that the tendency for a hemorrhagic pericardial effusion is greater among anticoagulated than among nonanticoagulated patients, but the fact remains that some nonanticoagulated patients with transmural myocardial infarction may suffer from acute hemorrhagic pericardial effusion on the basis of pericarditis.

Dissecting Aneurysm of the Aorta

Dissecting aneurysm of the aorta stands second only to rupture of the heart as a cause of nontraumatic hemopericardium. This condition occurs either in hypertensive subjects or in normotensive individuals with extreme degrees of idiopathic cystic medial necrosis of the aorta (Figure 13).

Some of the latter subjects show other physical signs of arachnodactyly* (Marfan's syndrome), while others do not.

In dissecting aneurysm of the aorta if external rupture of the aorta occurs, its site depends upon the site of the internal tear, as the two are closely related geographically. It follows that when a dissecting aneurysm of the aorta is responsible for hemopericardium the internal tear is usually in the ascending aorta. This is the same type of dissecting aneurysm in which the intramural hematoma may compress a coronary artery and in that way represent yet another basis for sudden death among subjects with dissecting aneurysm.

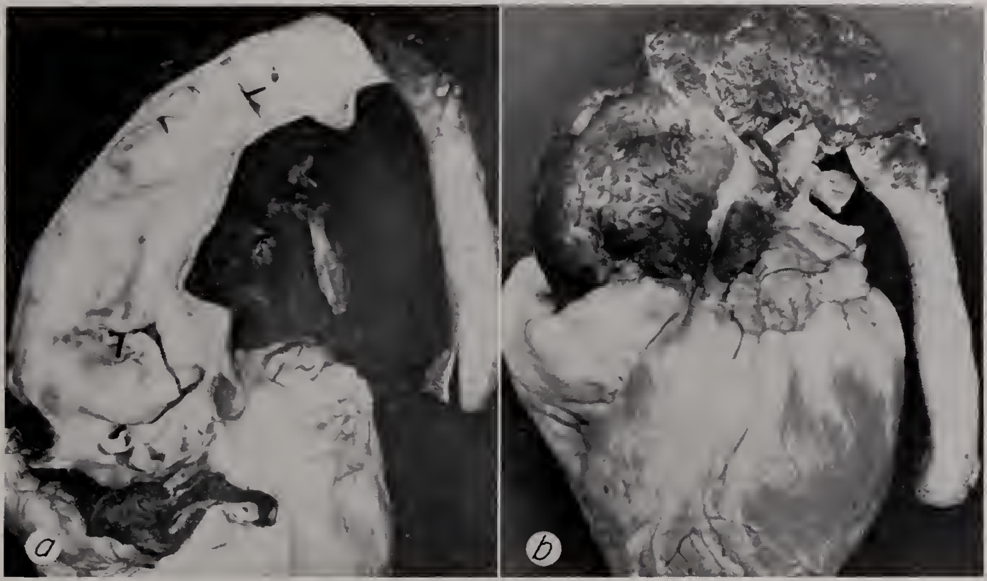

Fig. 13 — Hemopericardium resulting from dissecting aneurysm of the aorta in a 13-year-old boy with Marfan's syndrome. *(a)* The interior of ascending aorta and aortic arch. The rent, in relation to the lower probe, represents the primary internal tear of the dissecting aneurysm, while the rent at the upper probe represents a zone of "re-entry" of the false passage into the aortic lumen. Hemopericardium resulted from external rupture into the pericardial sac. *(b)* Exterior of heart and of thoracic aorta. The aorta adventitia is grossly distended with blood. Below the pericardial reflection a channel led into the pericardial sac and accounted for the acutely developing hemopericardium, which in turn led to sudden death.

Dilatation of Aorta

A less common cause of hemopericardium than myocardial infarction or dissecting aneurysm of the aorta is uniform aortic dilatation with rupture. Background conditions for aortic dilatation include syphilitic aortitis (Figure 14*a*), idiopathic cystic medial necrosis, and senile dilatation of the aorta (Figure 14*b*).

Hemorrhage

When rupture of a major artery is responsible for sudden death, the mechanism is usually one of mechanical interference with a vital structure by the resulting hemorrhage. The hemorrhage may compress the brain stem as in subtentorial hemorrhage. Reference to cardiac compression from hemorrhage has been made.

When bleeding occurs into a major airway the hemorrhage is responsible for asphyxia. Although simple exsanguination may cause sudden death, simple bleeding is usually associated with a recognized state of shock before death ensues.

A linear rent (between arrows) of the aorta led to hemopericardium. *(b)* In an 85-year-old woman with senile dilatation of the aorta, gross rupture (between arrows) of the ascending aorta led to hemopericardium and sudden death.

Obstruction of Valves of Pulmonary Vessels

Obstruction of the circulation sufficiently severe to cause sudden death takes several forms. These are (1) acute pulmonary embolism, (2) chronic pulmonary vascular obstruction and (3) valvular occlusion.

Acute Pulmonary Embolism

The most common type of pulmonary embolism is that in which the embolic material is represented by a noninfected thrombus. Important backgrounds for massive pulmonary embolism include cardiac failure or a surgical procedure, the latter particularly of an abdominal nature for malignant tumor. It is, however, to be recalled that a program of bed rest for almost any condition, including so simple a condition as acute respiratory infection, has at times become complicated by acute massive pulmonary embolism. The almost universal source for massive pulmonary embolism is the venous system of the lower extremities, even in cases of cardiac failure with right atrial mural thrombosis. Moreover, a point of significance is that venous thrombosis leading to pulmonary embolism need not be associated with obvious edema of either lower extremity.

In addition to the classic gross pulmonary embolism of bland thrombotic material there are instances of sudden death from unusual types of pulmonary embolism. These include embolism of gross masses of neoplastic tissue originating in the renal vein of a kidney with primary carcinoma. This event is most likely to occur when the kidney is manipulated surgically.

There is yet another form of embolism to the lungs of neoplastic tissue. This involves dissemination of small particles of tumor tissue into small pulmonary arteries and arterioles from a tumor which has invaded a vein. This type of spread is classically associated with a chronic state of pulmonary vascular obstruction,[10] but in an unusual instance the spread may be so extensive at one time as to be followed by death shortly after the event.

Embolism to the lungs of amniotic contents is recognized as a cause of sudden death in instances of difficult labor.

Chronic Pulmonary Vascular Obstruction

Sudden death is universally recognized as a consequence of acute pulmonary embolism. It should also be emphasized that sudden death may occur in instances of chronic pulmonary vascular obstruction, from whatever cause. Included in these are the pulmonary arterial obstruction that may complicate certain congenital anomalies such as septal defects or patent ductus arteriosus with pulmonary hypertension (Figure 15). The mechanism through which sudden death occurs under these circumstances is not clear but may represent acute right ventricular failure in the face of severe obstruction to ejection of blood from this chamber.

Mitral stenosis should be included in the broad category of chronic pulmonary vascular obstruction. In this condition sudden death may, perhaps, at times occur on the simple basis of pulmonary vascular obstruction. Usually, however, death occurring acutely in mitral stenosis is preceded by development of pulmonary edema.

Valvular Occlusion

A dramatic phenomenon is acute occlusion of a valvular orifice. It is hypothetically possible for such an event to involve any of the cardiac valves, but as a rule the mitral valve is the one affected.

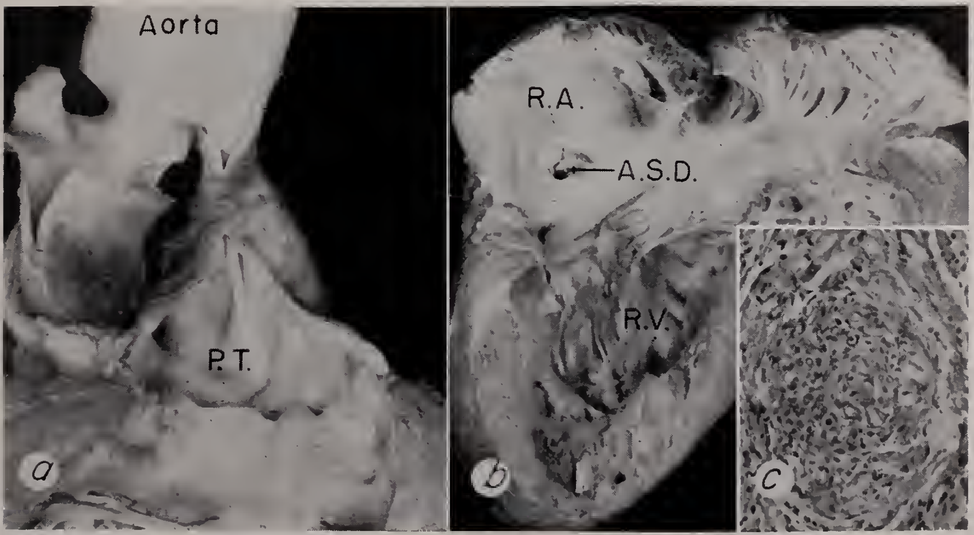

Fig. 15 — Patent ductus arteriosus with pulmonary hypertension in a 7-year-old boy who died suddenly. *(a)* The aorta and pulmonary arterial vessels (P. T.) are connected through a patent ductus arteriosus (containing probe). *(b)* Right atrium (R. A.) and right ventricle (R. V.). A small atrial septal defect (A. S. D.) is present. This may have been insignificant compared to the effects of the associated patent ductus arteriosus. The right ventricular hypertrophy is considered a sign of elevated pulmonary arterial pressure. *(c)* Photomicrograph of a small muscular artery of the lung. Characteristic plexiform lesion occludes lumen. This change is a characteristic of chronic elevated pulmonary arterial pressure. H & E; x200.

Continued

Two background conditions for this phenomenon exist. The first is mitral stenosis in which a left atrial thrombus occludes the valvular orifice. Classically, the thrombus has become detached from its zone of formation and lies free in the left atrium, a condition commonly called a ball valve thrombus. In uncommon instances of mitral stenosis a pedunculated thrombus may be so oriented as to be capable of occluding the mitral orifice.

The second condition which may occlude the mitral valve is the pedunculated left atrial myxoma (Figure 16). We have observed an instance of right atrial myxoma which obstructed the tricuspid orifice and caused a chronic impediment to the flow of blood through this valve. On hypothetical grounds, such a mass could cause sudden death by sudden occlusion of the valvular orifice.

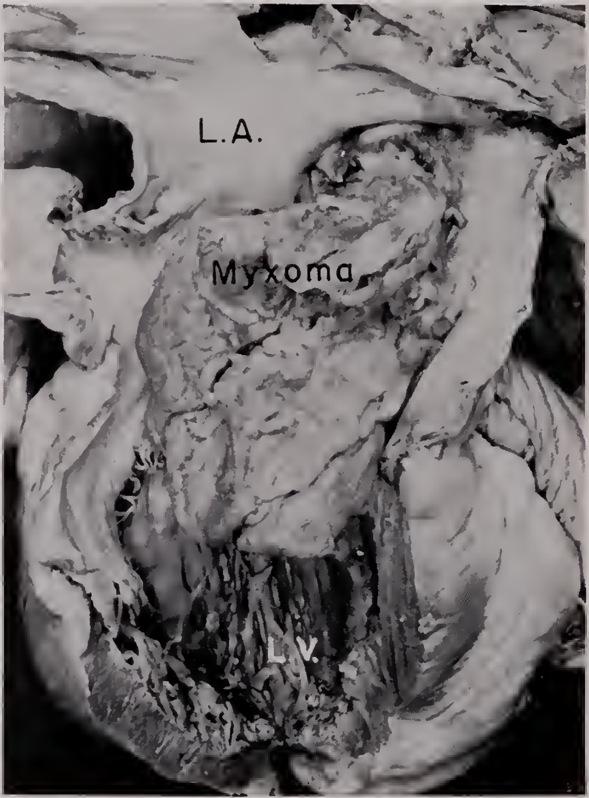

Fig. 16 — Myxoma of the left atrium occluding mitral valve in a 13-year-old girl. The myxoma is attached to the left atrial wall (L. A.) by a pedicle. The tumor engages and occludes the mitral orifice and was responsible for sudden death. L. V. = left ventricle.

In instances of sudden death from occlusion of a valvular orifice by a mass, a history of fainting spells is commonly obtained. This phenomenon is probably explained by the tendency for masses which occlude a valve to do so intermittently.

Summary

Sudden death may be caused by lesions involving the nervous, respiratory or circulatory systems. Lesions of the circulatory system numerically represent the largest group of conditions that may be responsible for sudden death.

Those processes of the circulatory system which may cause sudden death may be subdivided into the following four categories: (1) myocardial failure, (2) cardiac compression, (3) hemorrhage, (4) obstruction. The most common single basis for sudden death is that of myocardial failure which, in turn, is most often brought about by an arrhythmia in individuals with coronary atherosclerosis.

The Penalty of Overweight

In obesity, because of the increased work of breathing, the oxygen demand is greatly increased, so that respiration may not only be labored, but it may be inadequate and unable to support proper gaseous exchange in the lungs. Consequences may be serious.

Carbon Monoxide Intoxication*

Carbon monoxide is a colorless, odorless, nonirritating gas produced under conditions of incomplete combustion. Its danger as an acute intoxicant is well known; above half of the fatal poisonings in the U. S. are attributable to carbon monoxide. Less well known, however, is the ability of carbon monoxide to cause chronic poisoning through long-term exposure. As such it presents a serious public health hazard.

The most common source of carbon monoxide is motor-vehicle exhaust. The average motor vehicle produces exhaust which contains 3.5% carbon monoxide and 11.5% carbon dioxide. The ratio of CO to CO_2 is about 1:2 when the engine is idling, but decreases to 1:10 at cruising speed. As a crude approximation, exhaust gases are diluted about 1000-fold in the air adjacent to heavy traffic. In the absence of air movement, one would expect a fluctuation of the concentration of atmospheric carbon monoxide with the amount of motor-vehicle emission. The city of Los Angeles has a well known problem in regard to air pollution because of its peculiar geographic situation and the nature of the dominant air currents, in addition to its large number of motor vehicles. It is estimated that in Los Angeles motor vehicles emit 9000 tons of carbon monoxide per day, or about 20 tons per square mile.

Pathophysiology

The principal mode of action of carbon monoxide in the body is via a reversible combination with, and inactivation of, circulating hemoglobin, as represented by the equation $CO + HbO_2 \rightleftharpoons HbCO + O_2$. This was postulated as early as 1857 by Claude Bernard, who first suggested that carbon monoxide caused death from anoxia by preventing hemoglobin from carrying oxygen. At that time and for some years later it was believed that carbon monoxide had other specific effects upon various tissues and organs of the body. In 1895 Haldane exposed a mouse to a mixture of oxygen at 2 Atmospheres pressure and carbon monoxide at 1 Atmosphere pressure. Under such conditions it would be expected that most of the animal's hemoglobin would be in the form of carboxyhemoglobin; yet the animal re-

---

Continued

mained conscious and apparently normal. It was felt that compensation took place through a tenfold increase in the amount of oxygen carried in physical solution. Since the animal relied mainly on the physically dissolved oxygen, Haldane had demonstrated that carbon monoxide itself was not toxic but produced its lethal effects by blocking hemoglobin and causing anoxia. Although subsequent investigators have shown that the action of carbon monoxide in the body is not quite so simple, Haldane's experiments led to a philosophy of treating cases of severe carbon monoxide poisoning.

Absorption

In healthy young persons with relatively high-exposure levels, 30-50% of inhaled carbon monoxide is absorbed into the body. The rate of absorption is dependent on a number of factors: (1) the surface area of the gas-exchanging membranes of the pulmonary alveoli; (2) the rate of alveolar ventilation; (3) the rate of blood flow through the lung; and (4) the time required for blood to reach equilibrium with the carbon monoxide.

Affinity for Hemoglobin

The affinity of carbon monoxide for hemoglobin is 200-250 times that of oxygen. This in itself renders hemoglobin relatively unavailable for oxygen transport. In addition, however, the presence of carboxyhemoglobin produces an alteration in the oxygen dissociation curve of the uncomplexed hemoglobin, shifting it to the left so that there is a change in shape from a sigmoid curve to a hyperbola (Figure 1). Thus, except for extremely low oxygen tensions, the oxygen tension in the tissues will have to be lower for oxygen to be released from hemoglobin, and less will be released for a given fall in oxygen tension. This is known as the "Haldane Effect."

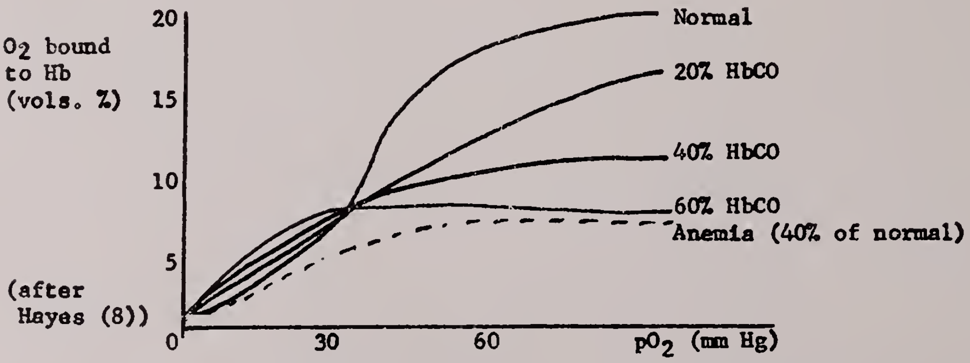

Fig. 1.

Excretion of Carbon Monoxide

Carbon monoxide is excreted predominantly via the lungs. Excretion depends upon alveolar ventilation and the oxygen tension in the inspired gases. In a resting subject breathing room air, the T½ of carbon monoxide elimination is 3-4 hours. Greater activity implies more rapid ventilation and circulation and, therefore, faster excretion. T½ may also be shortened through the substitution of pure oxygen or oxygen under increased pressure.

Since the body has a substantial reserve oxygen-carrying capacity, a small amount of carboxyhemoglobin is of little importance to healthy persons, but in anemic persons, or persons whose blood supply to the various organs is barely adequate, a small decrease in oxygen-carrying capacity may cause serious consequences. The equilibrium relationship between exposure and hemoglobin inactivation is such that 100 p.p.m. are associated with approximately 16% hemoglobin inactivation.

It has been known for many years that the body normally produces a small amount of endogenous carbon monoxide. This phenomenon was first clarified by Sjostrand[18] following the observation that persons with no known exposure to carbon monoxide contained small amounts of carboxyhemoglobin and expired small amounts of carbon monoxide. Sjostrand found that the carbon monoxide was produced during the breakdown of hemoglobin whether this occurred physiologically or pathologically. Engstedt[4] later described in quantitative terms the endogenous formation of CO in hemolytic disease. He found that roughly 0.5% of carboxyhemoglobin could be expected in normal persons and that in hemolytic anemia some subjects had values as high as 2%.

Affect on Eyes

The possibility that carbon monoxide can affect systems other than the hemoglobin system has long been the subject of speculation. Halperin's important study[7] demonstrated that carbon monoxide increases the visual threshold, which means an impairment of visual acuity under conditions of minimal illumination. He found that when oxygen was administered to his subjects and the carboxyhemoglobin level fell, visual thresholds temporarily improved, but that when oxygen was discontinued and room air substituted, the threshold returned to an intermediately impaired value, even though blood carbon monoxide levels did not increase. This suggested that some enzyme or other visual constituent was combining competitively with carbon monoxide and oxygen in the central nervous system or peripheral visual system. Cytochrome oxidase was considered, but rejected because of the fact that even in the absence of oxygen the pressure of carbon monoxide required to halfway saturate cytochrome oxidase is 20 times greater than that required to halfway saturate hemoglobin.

Effect on Muscles

Myoglobin or some similar substance appears to be the prime suspect now, although the affinity of carbon monoxide for this is also less than that for hemoglobin. Nonetheless, the combination of carbon monoxide with myoglobin in the muscles of the body is still postulated to account for much of the extreme muscle weakness which is such a prominent feature of carbon monoxide intoxication. In general, it is felt that it is possible for carbon monoxide to combine with any iron containing pigment, though only the importance of the combination with hemoglobin is well established.

Clinical Considerations

It is fairly certain that simple anoxemia plays the major role in the production of both the pathological lesions and the clinical symptoms of carbon-monoxide intoxication. Physical signs vary with blood levels, but exact correlation cannot be made due to varying states of health or

Continued

fatigue in the individual. Minimal toxicity to carbon monoxide starts at levels in the range of 20% with vague symptoms such as frontal headache, generalized weakness, fatigue, lassitude and drowsiness. These symptoms become progressively more severe when the concentration of carbon monoxide increases beyond 25%, and under these circumstances it is reasonably certain that the symptoms which develop are attributable to carbon monoxide. These may consist of vertigo, nausea, and vomiting.

Toxic Level for Carbon Monoxide

Alterations in physiologic functions are usually not found at levels of carboxyhemoglobin below 20%. Resting pulse, cardiac output and blood pressure are relatively unaffected until levels reach 30%. By 40-50% tachycardia and tachypnea are generally present, and coma ensues, with or without convulsions, at levels of 60-70%. It is generally agreed that a carbon monoxide level of 70% is incompatible with life.

Effect on Brain

It has been demonstrated that the higher centers in the brain are more sensitive to a decrease in blood-oxygen level than are other body tissues, including the lower centers in the brain. Therefore, psychomotor skills would be expected to be affected relatively sooner than others. Schulte[17] found a statistically significant correlation between low levels of carboxyhemoglobin and impairment of psychomotor function, but no correlation with physiologic function. Von Post-Lingen[21] demonstrated an increased threshold of flicker-fusion with carboxyhemoglobin levels below 25%.

Following carbon monoxide hypoxia there is a tendency for cerebral swelling to occur. This causes an increase in the oxygen pressure gradient between capillary and cells, thus producing a secondary hypoxia, which is caused by tissue factors and is independent of the oxygen transport function of the blood. This secondary hypoxia causes the post-anoxic headache which is characteristic after carbon monoxide poisoning, but which is not a part of the symptomatology of carbon monoxide hypoxia itself. Sluijter[19] has found that clinical improvement in cerebral manifestations of carbon monoxide poisoning is closely correlated with improvement in the electroencephalogram. The most characteristic sign is increased voltage of the alpha waves during treatment of patients who are conscious but complaining of severe headache.

Effect on Heart

Electrocardiographic changes in carbon monoxide intoxication are again related to anoxia. Disturbances of rhythm, disturbances of conduction, and ST segment changes may all be present. The specialized conducting system has been said to be the most vulnerable cardiac tissue.

Cosby and Bergeron[1] showed that in dogs the acute and chronic changes were somewhat different. In their acute experiments, T wave and ST segment changes appeared at carbon monoxide levels of 40%, with heart block occurring only with levels above 75%. Necrosis in the myocardium was the characteristic pathological finding. In the chronic experiments, T-wave changes occurred after a week's exposure at 20% concentration, and degeneration of myocardial fibers was the common finding.

In humans it is found that the height of the T wave begins increasing at around 15%. Slight depression of the ST segment ensues at around

35%, and the T waves become diphasic, then inverted, in the 45-60% range.

Chronic Exposure

The whole question of the existence of a chronic state of carbon monoxide intoxication has been subject to much dispute. Katz[9] feels that chronic intoxication constitutes a distinct clinical entity, and he has set down certain criteria for making this diagnosis. These are as follows: (1) blood carbon monoxide of 10% or more; (2) one or more of the following symptoms: headache, dyspepsia, weakness or dizziness; (3) clearing of symptoms 4-7 days after removal from exposure, with daily inhalations of carbogen (95% 0_2 + 5% CO_2); (4) no other medication necessary; (5) freedom from symptoms following reduction of the blood level of carboxyhemoglobin to less than 10%.

Killick,[10] investigating the question of tolerance, has shown that if you expose a person to identical levels and durations of carbon monoxide on several consecutive days, the amount of carboxyhemoglobin resulting from later exposures will be only a fraction of that resulting from the first exposure. Studies of red blood-cell uptake and equilibrium constants in vitro have shown no alterations in these processes. Therefore Killick has felt that either there are changes in the diffusion of carbon monoxide into the blood, or else some metabolic destruction of carbon monoxide occurs. Morgan,[15] on the other hand, is convinced that a compensatory polycythemia takes place. The problem has not yet been resolved.

Treatment

The philosophy of treatment of acute carbon monoxide poisoning has evolved mainly from Haldane's classical mouse experiments. By allowing a patient to breathe oxygen at hyperbaric pressures (usually 2 Atm.), not only may sufficient oxygen be dissolved in the plasma to correct the anoxia rapidly, but also the dynamics of the reaction $CO + Hb0_2 \rightleftharpoons HbCO + O_2$ will be altered so as to give an increased yield of hemoglobin freed from carbon monoxide. This in turn will cause a movement of the oxyhemoglobin dissociation curve of arterial blood back to the right. Secondary hypoxia is also opposed to some degree by the application of high pressure oxygen. Thus in severe cases there is some rationale for giving high-pressure oxygen despite the fact that some of the damage is irreversible.[19]

Oxygen Under Hyperbaric Pressure

Although oxygen under high pressure is generally considered the treatment of choice in severe carbon monoxide poisoning, there is the obvious limitation that relatively few medical centers have hyperbaric chambers, and these are expensive to use. Consequently, alternative approaches have been suggested. Since 1920 much has been written about carbogen (95% O_2 + 5% CO_2) as an effective treatment.[3] The philosophy here is that a small amount of carbon dioxide acts as a mild respiratory stimulant, and thus the blood will be cleared of carbon monoxide faster than with oxygen alone. The method has been condemned by some on the ground that a patient with respiratory depression is already suffering from the effects of an excess of carbon dioxide in his tissues. Nonetheless, the method is still in use and is generally considered beneficial.

Continued

Mercury Vapor Light

Haldane was the first to observe that strong light could be used to accelerate the dissociation of carboxyhemoglobin. The optimal wave lengths for this are 400-430 mμ and 540-570 mμ, and these wave lengths can be obtained using a mercury vapor lamp. Dog experiments have shown that a pump oxygenator along with a facility for exposing the blood to a mercury-vapor lamp can be an extremely effective method for clearing the blood of carbon monoxide.[12] Hypothermia may be used in conjunction to reduce the tissue requirements for oxygen.

Succinic Acid

Although the treatment of acute poisoning by general supportive measures has long been followed, little work has been done on methods of returning the patient quickly to the conscious state. Succinic acid, a powerful respiratory stimulant, has been shown to have beneficial effects in the treatment of coma induced by barbiturates, morphine, insulin, and alcohol, provided failure of the respiratory center has not occurred. Gershon[5] also found it to be of value in shortening the time for return of reflexes in severe carbon monoxide poisoning. Besides its ventilatory effect, succinic acid tends to favor oxyhemoglobin over carboxyhemoglobin in the presence of both carbon monoxide and oxygen in alveolar air and has a direct stimulatory effect on cellular metabolism, particularly in the central nervous system and the functional tissues of the heart.

Sequelae

The question of sequelae resulting from carbon monoxide intoxication has been reviewed by Pfrender.[15] Most investigators agree that sequelae are due to oxygen lack during the acute episode and are related to the length of the period of unconsciousness. It is estimated that permanent sequelae occur in 0.2% of acute poisonings. These usually are neurologic and occur some weeks after the acute episode. Parkinsonism, psychoses, confusion, loss of judgment, amnesia, blindness or partial blindness, and damage to the heart are among the most common sequelae. There is still speculation as to whether these represent specific histotoxic effects of carbon monoxide, as might be suggested by the delay in the onset of symptoms, or whether they fit into the classification of chronic carbon monoxide poisoning, secondary to entrapment of carbon monoxide.

Case Reports

Case No. 1

A 36-year-old separated female under psychiatric care was admitted to another hospital on 11/14/63 after being found comatose in a closed garage with her car running. Artificial respiration was administered by the police, and upon admission to the hospital, blood pressure was 96/60, pulse 110 and respirations 12 and shallow. She was not cyanotic, but was lethargic and complained of nausea and vertigo. She vomited once. Nasal oxygen was administered and by the fifth hour of admission she was oriented and able to take fluids. Physical examination the morning after admission was essentially negative except for pale eyegrounds on funduscopic examination. Hemoglobin was 14, red blood cell count 4 million and white blood cell count 12,500 with normal differential.

The patient was transferred to Mount Sinai Hospital that day, still complaining of headache and nausea. Complete neurological examination was done and was normal except for hyperactive deep tendon reflexes. Spinal tap was normal. An electroencephalogram on the third day of admission showed diffuse low voltage with some increase in voltage following hyperventilation. By the third week of hospitalization the electroencephalogram had virtually returned to normal.

Approximately one week after admission the patient began complaining of a "curtain" in front of her eyes, but ophthalmologic consult revealed no objective evidence of eye difficulty. By the time of discharge, 12/5/63, she was relatively asymptomatic.

Case No. 2

A 42-year-old mechanic and automotive instructor was admitted to Mount Sinai Hospital on 3/30/65 because of symptoms of nausea, epigastric distress, dizziness and chronic fatigue of one year's duration. He also complained of a "loss of circulation" in his arms and legs with frequent episodes of numbness and tingling of the hands, relieved by exercise. His gastrointestinal symptoms were usually relieved by Gelusil and Alka Seltzer, although at times, especially at night, relief was unsatisfactory.

The remainder of the history and all physical findings were unremarkable. Laboratory data revealed hemoglobin of 15.3 gm.%, white blood cell count of 7300 with normal differential, urinalysis normal, serology negative, sedimentation rate 24, stool guaiac negative. Twelve-hour gastric analysis showed a volume of 705 ml. with 74° free acid and 83° total acid. Chest X ray and oral cholecystogram were normal. Stomach X rays demonstrated an ulcer of the lesser curvature of the antrum. Because of the history of chronic exposure to motor-vehicle exhaust, a blood carbon monoxide level was drawn which was 15% (normal less than 5%).

During the hospitalization the patient's gastrointestinal symptoms cleared rapidly on an ulcer regime. He was advised to avoid motor-vehicle exhaust as much as possible.

For Squashed Legs and Diseased Toes

Among the ancient Egyptians squashed leg must have appeared to be rather a minor injury — expected to respond to such a simple remedy as:

Chopped-up Chaff soaked in Water.

Lay thereon as a Poultice in order to heal him at once. It is also to be used for any Limb that thou wishest.*

Diseased toes, however, required a more formidable prescription compounded of 18 ingredients, some of the more bizarre of which were incense, Resin-of-Acanthus, Fat-of-the-Cedar-Tree, and Water-from-the-Rain-of-the-Heavens — all to be blended into a poultice and applied to the afflicted toes for four days.

Sufficient for corns was a poultice of berries and cow fat.

Hemolytic Anemia and Open Heart Surgery

ROBERT A. GREEN, M.D.
St. Louis Park, Minnesota

MECHANICALLY INDUCED hemolysis of red cells related to cardiac bypass and prosthetic repairs in the heart is a relatively new problem in clinical hematology. New syndromes are being seen in which it appears that hemolysis results from mechanical trauma to red cells as a direct consequence of the surgery. Hemoglobinemia and hemoglobinuria occur routinely following extracorporeal circulation,* and although they are for the most part transient, there is sufficient injury to red cells not immediately destroyed during the pump run to shorten their life span appreciably. Accelerated red cell destruction in these circumstances may not result in anemia, however, because increased marrow function may compensate for it.

Early Studies

Experimental studies to evaluate the role of mechanical factors in hemolytic anemia following open heart surgical procedures were reported in 1956 by Stohlman et al.,[1] who showed that inserting a lucite prosthesis with the Hufnagel ball valve in the left ventricle of dogs would produce hemolytic anemia. They considered the cause to be mechanical injury to the red cells from impact of the ball against the valve housing. Rose[2] noted postoperative anemia in patients with Hufnagel ball valves placed in the thoracic aorta for the treatment of aortic insufficiency.

The anemia of the post-perfusion syndrome, described by Kreel[3] in 1960, was thought to be due to trauma to red cells, but it was transient and not severe. Prolonged cases of hemolytic anemia of apparently mechanical origin, however, have been reported during the past few years following open heart surgery. The more severe and prolonged cases have occurred mainly in patients who have had Teflon patch repairs of septal defects and in patients who have had aortic valve replacement.

Causes of Mechanical Hemolysis

The cause of mechanical hemolysis in pumps and tubes, or under other experimental conditions, is not completely understood. Cell lysis may occur because of currents and turbulence and because of other physical influences, such as shear stress, pressure differences, interfacial tensions. In clinical cases, factors of turbulence seem to play the major role, although in some of the Teflon patch cases, hemolysis may be due to impact of red cells on exposed areas of the Teflon patch. In other cases where the Teflon has been completely endothelialized, the problem appears to result from jet stream turbulence through defects in the valve-septal attachment.

Hemolytic Anemia Following Repair of Septal Defects

The first case of severe hemolytic anemia occurring as a complication of open heart surgery in humans was reported in 1961 by Sayed et al.[4] in a patient who had undergone Teflon felt patch repair of an ostium primum defect. Seven cases with similar features have now been reported.[4-7] Morphologic abnormalities of the red cells (fragmentocytes, burrs, helmet cells) and evidence that the hemolysis is intravascular have suggested that it is mechanical in origin and related in some way to the operation. There has been no evidence in these cases that the anemia is autoimmune, and it does not respond to corticosteroids. Two patients have undergone spontaneous partial remission, and five cases have been reoperated. At reoperation, regurgitant jets of blood striking the Teflon patch have been found coming either through cleft aortic cusps of the mitral valve, or through openings where the patch had torn loose from its moorings. Hemolysis in these is considered to be due to impact of the red cells on the patch or to turbulence alone. Two patients recovered fully after reoperation, one of them after covering a bare area of Teflon on the patch with atrial endocardium, the other after anchoring the part of the Teflon patch which had pulled away from the mitral valve attachment. Three other reoperated patients died.

Hemolytic Anemia Following Aortic Valve Replacement

Hemolytic anemia due to mechanical factors alone has also been reported following other types of open heart surgery, notably in cases of aortic valve replacement, when for one reason or another aortic insufficiency persists after operation. In these cases antiglobulin tests are negative; the anemia does not respond to corticosteroids and improves only after the mechanical defect is corrected at reoperation.

Autoimmune Phenomena

Pirofsky[8] has recently described another group of cases of hemolytic anemia following aortic valve replacement which differs from the above in terms of clinical course, serologic tests, and responsiveness to corticosteroids. The clinical course and serologic tests in these cases suggest that autoimmune phenomena are responsible rather than purely mechanical factors. Characteristically, anemia appears fairly early in the postoperative course and is variable in duration and severity, but does not result in death. In four of seven cases, the febrile-lymphocyte-splenomegaly syndrome was also present. Erythrocyte morphology in these cases was not described, although in a personal communication the author stated that he did not feel that at this time the absence or presence of fragmented cells should be used as a differential point between the mechanical and antibody form of hemolytic phenomena.

In contrast to the cases thought to be due to mechanical factors alone, antiglobulin tests were positive in six of seven of these cases, although the reactivity was said to be weak. Because of this and the variability of commercial antiglobulin sera, it is suggested that a battery of tests be performed to detect the positive serologic reaction. These cases also differ in their response to corticosteroids. In four cases in which it was used, prednisone was helpful in correcting the hemolysis.

How and why an autoimmune state develops following aortic valve replacement remains a matter of speculation. It seems unlikely that it is due to infusion of foreign lymphocytes from the large amounts of blood used during surgery, since it does not occur in other types of open heart surgery. The authors speculate that mechanical injury of red cells by turbulence may alter red cell-surface antigens in such a way that they then induce formation of auto-antibodies which are responsible for hemolysis.

Hemolytic Anemia in Valvular Heart Disease Unrelated to Surgery

If turbulence resulting from aortic valve prostheses can produce sufficient injury to red cells to shorten life span and cause hemolytic anemia, one might expect to find this in some cases of rheumatic valvular disease unrelated to surgery. One such case with morphologic changes suggesting red-cell trauma as the causative factor has been discussed by Dameshek.[9] In a study of rheumatic valvular disease by Brodeur et al.,[10] 15 of 21 cases were found to have significantly shortened red-cell survival, although none were significantly anemic. Aortic lesions were considered to be principally responsible for the turbulence resulting in red-cell injury. It seems quite possible that further search may turn up additional cases with significant anemia.

Summary

Hemolytic anemia due to injury of red cells following open heart surgical procedures is a relatively recent development in clinical hematology. Cases have been described in which mechanical factors alone appear to be responsible for hemolysis in some; whereas in others, an autoimmune state is said to be produced, the pathogenesis of which is not clear.

The former frequently require reoperation for correction of a mechanical abnormality producing undue turbulence of blood flow. They are serologically normal and do not respond to corticosteroids.

The latter do not require reoperation, show positive antiglobulin tests, and tend to respond to corticosteroids.

Additional cases of hemolytic anemia due to red-cell trauma are likely to be found among cases of rheumatic valvular disease, primarily with aortic lesions, unrelated to surgery.

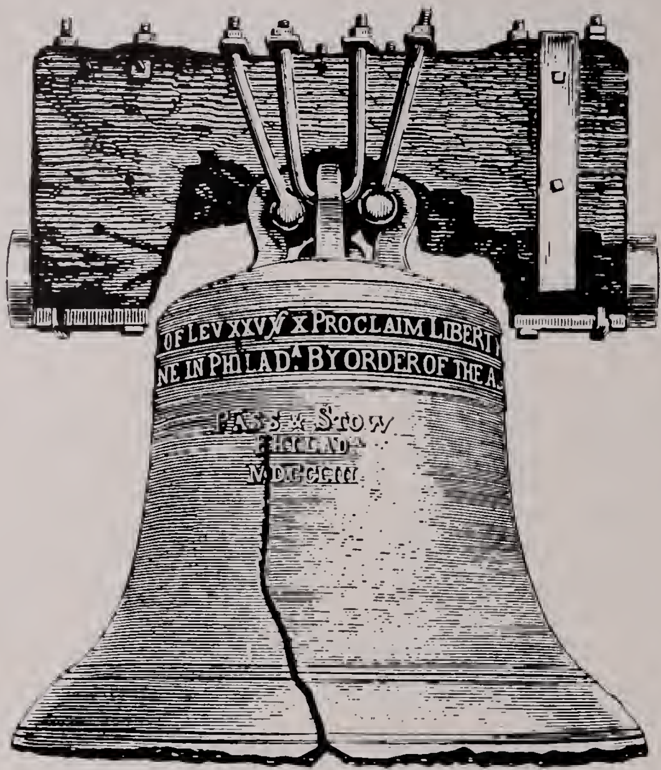
19th CLINICAL CONVENTION OF THE AMA



OF LEV XXV V X PROCLAIM LIBERTY
NE IN PHILADA BY ORDER OF THE A
PASS & STOW
PHILADA
MDCCLIII

PHILADELPHIA, PA.—NOV. 28-DEC. 1, 1965

Plan to attend the world's most comprehensive four-day postgraduate course in recent developments in medical science, and participate in the observance of the founding of the first medical college established in this country—the Medical School of the University of Pennsylvania.

This postgraduate refresher course, conducted by the nation's outstanding medical authorities, will be presented for you in historical Philadelphia. Philadelphia has many luxurious hotels and colorful restaurants. Mail the enclosed registration and room reservations coupons now!

TWO POSTGRADUATE COURSES: Gynecology and Obstetrics; and Cardiovascular Therapeutics (each to be presented in 3 half-day sessions) BREAKFAST ROUNDTABLE DISCUSSIONS: Gynecologic Difficulties in the Adolescent • Early Management of Traffic Accident Patients • Common but Worrisome Pediatric Problems •The Nature of Chronic Bronchitis and Pulmonary Emphysema • Prevention of Long Term Illness: A Practical Approach • Clinical Uses of Electroencephalography SCIENTIFIC SESSIONS: Ulcerative Colitis • Pediatrics • Chemotherapy of Cancer • Preventive Surgery in Cancer • Bacterial Infections • Ultraviolet Irradiation in Medicine • Genetics • Current Status of Drug Therapy in Rheumatology • Psychiatry • Urology • Gastrointestinal Surgery • Cardiovascular Surgery • Current Concepts of Shock • Computers in Medicine • Pain in the Back • Orthopedics • Common Otology Problems • Eye Problems and the Non-Ophthalmologist • CLOSED CIRCUIT COLOR TELEVISION • MOTION PICTURE PREMIERES • Hundreds of SCIENTIFIC AND INDUSTRIAL EXHIBITS

The complete scientific program, plus forms for advance registration and hotel accommodations, will be featured in JAMA October 25

Abstracts, Briefs and Commentaries

MAMMOGRAPHY NOT INFALLIBLE

Mammography is not, as yet, a screening technique. It is not a simple nor inexpensive procedure. It will not be done by every radiologist. It does not replace biopsy of suspicious lesions.

Selected radiologists (after an instruction course by Dr. Egan) were able to correctly diagnose malignancy in 79% of 475 proven malignancies of the breast. As of now, it is probably agreed that some assistance from mammography may be seen in the following conditions:

1. Women who are difficult to examine because of large breasts
2. Deep-seated lesions
3. Indeterminate lesions
4. Study of the second breast when one breast has been removed for cancer.

INCOMPATIBILITY OF INTRAVENOUS SOLUTIONS

For a thesis, Misgen* has studied some of the visible signs of incompatibilities of 34 commonly used intravenous drugs. A thorough pharmacologic testing of all possible drug combinations would be of astronomical proportions if more than two drugs were included in each combination. If one were to test 100 drugs and crossmatch three at a time, a total of approximately 162,000 combinations would be possible.

Misgen has provided a table starring the incompatibility as indicated by particulate matter observed in the solutions when they were crossmatched. This table should be of value to pharmacists or anyone who mixes various intravenous solutions.

It would be well for all doctors when giving mixed intravenous solutions to observe the solution for particulate matter before administration.

Carl O. Rice, M.D.

---

PROTEIN LOSS IN MALIGNANCY

Malignant lesions of the gastrointestinal tract are commonly associated with hypoproteinemia. Sixteen patients with carcinoma of the gastrointestinal tract and three with carcinoma elsewhere were studied. The protein loss into the gastrointestinal tract and albumin degeneration rate were measured in a series of patients with I^{131}-labeled albumin. Excessive loss of protein into the intestine was demonstrated in two cases of carcinoma of the stomach, one of the esophagus, and one of the colon. In one patient resection of the colon lesion resulted in a remarkable reduction in protein loss. It is suggested that the major source of protein loss is the tumor itself and adjacent mucosa.

GASTROINTESTINAL BLEEDING OF "UNKNOWN ORIGIN"

Gastrointestinal hemorrhage in the pediatric age group, particularly that of rectal issue, is studied by comparison of three case series, including 48 cases of bleeding Meckel's Diverticulum, 16 cases of peptic ulcer, and 79 cases of bleeding due to "unknown cause." The mathematical probability of finding a Meckel's Diverticulum at laparotomy for rectal bleeding is calculated for this series, and the rate of diagnostic accuracy is found to be less than 66%. The probabilities of origin of hemorrhage in the "unknown bleeder" are discussed. The conclusion is reached that larger numbers of such cases than heretofore realized are probably because of acute peptic ulceration of the stomach or of the duodenum. Certain clinical recommendations are made based upon this hypothesis.

Brayton, D.: Amer J Dis Child 107:287, 1964

CONTROLLED TRIAL OF PROPHYLACTIC PORTACAVAL SHUNT SURGERY

The Boston Inter-Hospital Liver Group has conducted a controlled hospital trial of prophylactic portacaval shunt surgery in patients with cirrhosis and esophageal varices. The first 50 patients are reported. There were nine deaths among 28 patients who were operated on, and eight deaths in the 22 controls. Five massive hemorrhages occurred among the controls, three of which were fatal, and two massive hemorrhages, probably from duodenal ulcer, in the surgical group. Varices have persisted unchanged in only two of the 19 survivors in the group operated on, and in 11 of the 14 survivors in the control group. Hepatic precoma is a continuing problem in four of the surgical and in one of the control patients. The over-all survival is greatly improved in patients who were selected for this study when compared with the whole population with esophageal varices, but within the study no significant difference is yet apparent between the surgical and control patients. A longer follow-up and a larger number of patients are needed.

ULTRA SOUND

An *International Conference on Diagnostic Ultrasound* was held at the Pittsburgh Hilton Hotel on May 20-22, 1965. The conference was well attended by overseas representatives with the exception of Russia.

The use of diagnostic ultrasound in medicine has now reached a stage of acceptance by our profession to encourage production of commercial medical instruments.

Clinical papers reporting the use of ultrasound in locating and removing foreign bodies in the eye, measurement of the size of the eye and the diagnosis of intraocular and extraocular pathology were given.

The diagnostic value of displacement of the mid-line echo by space-occupying lesions and measurement of the lateral ventricles of the brain were described. The use of ultrasound for the measurement of the mitral valve and for the study of other functional cardiac pathology was reported.

Papers on the diagnostic value of ultrasound in the study of abdominal organs such as the liver and spleen were not too encouraging with present techniques. A special paper on the toxicity of ultrasound at diagnostic power levels revealed absolutely no trace of harm. This was a monumental and exhaustive study supported by Smith Kline Instrument Company.

Considerable advances were reported in the use of ultrasound in studying the contents of the female abdomen in gynecological and obstetric conditions. Scottish and Australian work was the most outstanding. The contents of the pregnant and nonpregnant uterus in the later stages of uterine enlargement were easy to differentiate. Hydatidiform mole was clearly seen as a "snow-storm" in the uterus as opposed to fetal parts. The early pregnant uterus could be seen through a full bladder. A number of commercially available instruments used in most of the clinical studies were introduced.

At the workshop conference at the end of the meeting future needs and further development were vigorously discussed.

J. J. Wild, M.D.
Minneapolis, Minnesota

NICOTINIC ACID IN HYPERCHOLESTEREMIA

Forty-one patients with hypercholesteremia and peripheral or coronary arteriosclerosis were treated with 1.5-7.0 gm of nicotinic acid daily for 6 years. Rapid reduction of cholesterol and all lipid fractions was achieved in all patients without change in diet. Three deaths from arteriosclerotic heart disease occurred shortly after onset of therapy, but none thereafter. While on therapy all patients had normal lipid levels. Acanthosis nigricans was seen in four patients and disappeared promptly on discontinuation of therapy. Diabetes mellitus was temporarily aggravated in three of five patients. This medication seems singularly well-suited for a wide range study on the influence of reduction of cholesterol levels on life expectancy.

Mahl, M., and Lange, K.: Amer J Med Sci 246:673, 1963

TRUNCAL SHOTGUN WOUNDS

These are characteristically civilian or "peace time" wounds, but many resemble war injuries, with extensive tissue loss or destruction and multiple injuries. The broad shot pattern frequently leads to thoracico-abdominal injury and often results in multiple organ and also multiple system injury with involvement of cardiovascular, respiratory, gastrointestinal, and neurologic systems. These wounds are usually associated with extremely high morbidity and mortality rates. The weapon is frequently chosen by those making a sincere attempt at suicide. Sporting shotgun accidents are commonplace.

Hospital records of 1,487 patients were reviewed. One hundred fifty-four wounds were inflicted with shotguns. One hundred and three of these involved the trunk and serve as the basis of this report. Sixty-seven per cent of such wounds were in Negroes. One hundred and three who sustained shotgun injuries survived long enough to reach the hospital. Eighty-one patients with truncal wounds survived, while 22 died, a survival rate of 79 per cent. A 12-gauge weapon with No. 6 shot was most popular. Five patients had self-inflicted wounds as a suicide attempt. The severity of this type of injury lessens as the distance between the gun and the patient increases, due to scattering of the pellets.

Patients were placed into four groups according to the type of therapy employed:

Group I

Patients in this group were less severely injured; their wounds with tetanus prophylaxis were treated locally together with observation during course of recovery. There were 12 patients with 100 per cent recovery in this group.

Group II

These were more severely injured persons who did not require major surgery. There were 11 patients with 100 per cent recovery; one patient required bilateral tube thoracostomy for bilateral hemopneumothorax.

Group III

Nineteen patients underwent a major procedure requiring general anesthesia but not involving the pleural or peritoneal cavities. These procedures generally required immediate debridement of wounds plus exploration of major vessels in the neck or groin. Three patients required tube thoracostomy; ten required blood transfusions. There were 16 survivors and three deaths. The survivors received an average of 1500 cc. of blood, and those who expired an average of 4000 cc. Eight major complications developed in six patients. Twelve secondary operations were performed on eight patients.

Group IV

This group of 61 patients included those who required abdominal, thoracic, or thoracico-abdominal operations. There were 42 survivors and 19 deaths. Thirty-two injuries were confined to the abdomen, 25 were thoracico-abdominal, while three were thoracic only. Sixteen patients undergoing laparotomy required tube thoracostomy also. The colon and small intestine were involved in 32 patients. The liver, stomach, and kidney were involved in 19, 15, and 14 cases, respectively. Injury to the diaphragm occurred in 13 cases and to the spleen in 10 cases. In most cases more than one organ, sometimes several, were involved.

Survivors in this group received an average of 2750 cc. of blood, while those who did not survive received an average of 4500 cc. Twenty-eight patients had a major body-wall defect requiring some type of reconstructive procedure to close; sixteen of these defects were in the chest wall and 12 in the abdominal wall. Forty-one major complications developed in 28 patients. Four patients had evisceration when admitted. There occurred six fecal fistulas in four patients, two of whom expired. Two patients developed massive upper gastrointestinal hemorrhage and both died. One patient with biliary fistula following extensive liver damage survived with spontaneous closure of the fistula. There were seven pulmonary complications. One patient died from pneumonia, and one with infection of the abdominal wall with gas-forming organisms following a colon resection. Postoperative complications were considered the cause of death in 10 of 22 patients who expired. Secondary plastic operations were frequent. Two arteriovenous fistulae were excised.

Shotgun wounds are a distinct injury, different from other penetrating wounds or those caused by other types of firearms. Multiple organ and multiple system injuries are common. Thoracico-abdominal wounds are frequent. Body-wall defects demand reconstructive closure. Complications are common and frequently the cause of death. Secondary surgery is often required. Successful management demands rapid institution of effective resuscitative measures and a broad surgical knowledge.

Minneapolis, Minnesota

Fitzgerald, John B., Quast, Don C., Beal, Arthur C., Jr., and DeBakey, Michael E.: Surgical Experience with 103 Truncal Shotgun Wounds. J Trauma, January 1965

ANESTHESIA IN HEAD INJURIES

Proper anesthetic management of patients with head injuries and associated trauma requires that a philosophy of total patient care be practiced. Repeated evaluation of physical, hemodynamic, and neurological status is required. The presence of shock in patients with head injuries usually indicates associated, more serious injuries which must be sought and treated or excluded. Anesthetic management and priority of treatment of multiple injuries are enumerated. General anesthesia is usually preferred and has not increased the severity of neurological impairment due to trauma.

Journal of the American Medical Association

Tate, N.: Lancet 2:1090, 1963

PANCREATIC BIOPSY

Of 159 patients undergoing pancreatic biopsy, the complication rate was 9.5% and the mortality rate was 3.8%. There were three deaths in 25 Silverman-needle biopsies and two deaths in 130 wedge biopsies. The chief complication from this procedure is pancreatitis. Pancreatitis following a needle biopsy is due to the needle's entering a part of the duct system and the consequent escape of pancreatic juice into the substance of the pancreas. Thus, pancreatitis can develop without a fistula. This has been true even with transduodenal needle biopsies. Because of its risk, pancreatic biopsy should not be performed indiscriminately. It should not be done for unresectable lesions nor should it be used for resectable lesions which clinically appear to be carcinoma. Biopsy of the pancreas should be reserved for those resectable lesions which do not have the obvious clinical features of neoplasm.

SIGMOID VOLVULUS

On the basis of this review and experience, a plan for treatment of sigmoid volvulus was established: 1) immediate operation for acute, fulminating type; 2) nonoperative decompression of the volvulus with proctoscope and rectal tube for subacute, chronic type, followed by elective resection in seven to ten days in most instances. In the series reported, where gangrenous bowel was suspected, where proctoscopic decompression was unsuccessful, or where at proctoscopy the mucosa appears friable, discolored, or bloody, laparotomy was indicated. If the bowel was viable at surgery, operative detorsion was done with a rectal tube threaded past the twist and sutured in place at the anus. If the bowel was gangrenous, then an obstructive resection was done. In those cases successfully reduced, where age or other radical conditions contraindicate elective resection, a low-fiber diet and wetting agents were of benefit.

SURGERY OF FACIAL FRACTURES — **Reed O. Dingman, M.D. and Paul Natvig, M.D. W. B. Saunders Co. Philadelphia, $22.50.**

This volume presents a thorough resume of the modern management of simple and severe facial fractures. Though it is most useful to the plastic and maxillofacial surgeon, basic fundamentals are emphasized, making it a valuable reference work for general surgeons, surgical specialists and dentists treating facial injuries.

Separate chapters dealing with dental occlusion and intermaxillary fixation are detailed and well illustrated. These fundamental aspects of fracture reduction and fixation are adequately emphasized.

The diagnosis of these fractures can often be made on clinical examination, but roentgenographic confirmation is necessary. To satisfactorily visualize these difficult areas diagrams of the various roentgenographic positions are included.

The basic methods of reduction and fixation of facial fractures is thoroughly covered. Open operation at fracture sites with fixation of the bony fragments with stainless steel ligatures is well discussed and illustrated. Also included is a separate chapter on the more difficult problem of facial fractures in children. And last but not least, the authors have prefaced the text with several profiles of pioneers who have laid the foundation for modern care of facial bone injuries.

INDUSTRIAL AND TRAUMATIC OPHTHALMOLOGY — **Symposium of the New Orleans Academy of Ophthalmology. C. V. Mosby Co., St. Louis, 1964. 321 pages. Illustrated, references, index. Price $14.50.**

This book will find wide use among industrial physicians, compensation experts and ophthalmologists. Seven experts in this broad field have contributed chapters and a round table discussion on the following subjects: Plant vision safety and screening; emergency eye care; visual requirements of driving; lead trauma involving the eyes; chemical and radiant energy injuries; protective eye wear; disability rating of eye injuries; immediate and delayed pathology of ocular trauma. The subjects are presented in detail. The volume is well edited and illustrated. To my knowledge there is no comparable work available.

BAHAMA INTERNATIONAL CONFERENCE ON BURNS — **Dorrence and Co., 1964**

This conference on burns was conducted by a group of physicians who could speak authoritatively on each of these problems relative to burns.

The monograph deals with the entire problem of burns and includes some well-documented research work.

Clinical application to the treatment of burns has been adequately detailed and illustrated. Treatment of shock and fluid imbalance are also described. A few color illustrations add some charm.

For the plastic surgeon who has some interest in the practical application of his art, this monograph should serve an excellent purpose. To other physicians who are interested in the burn problem, this book should be well worth a few hours of concentrated study.

OUTLINE OF UROLOGY — **C. D. Creely, McGraw Hill Book Co., Toronto, 1964. p. 385.**

This pocket-sized textbook of urology is beautifully bound, well illustrated and succinctly written in the very excellent manner in which the author has conducted his teaching at the University of Minnesota Medical School.

This book should be on the office shelves of every practitioner who may from time to time desire some brief enlightenment in the field of urology. For the medical student who is becoming acquainted with his clinical material, this is an invaluable textbook, concise, well organized and adequately illustrated with line drawings or X-ray films. The references and bibliography at the end of each chapter are sufficient for anyone who wishes to make a more detailed study. The index is well done.

Family Planning in the City-County Hospital Setting

- A
- Preliminary
- Report

ERICK Y. HAKANSON, M.D.*
St. Paul, Minnesota

ONE OF the necessary responsibilities of an obstetrical department in the maintenance of optimum health for the indigent and disadvantaged patient is to provide help in family planning.

Unfortunately, in the past, contraception has been such a controversial subject that meaningful discussion of it has been limited to the scientific community and has been shunned by politicians and government officials at all levels. This lack of public awareness has led to vast areas of ignorance, misinformation, and apathy. These facts, together with political and religious opposition, have relegated birth control largely to a matter of private initiative. The result has been that those patients who were able to afford private care were able to take advantage of whatever scientific information and/or techniques were available, whereas the indigent patient had nowhere to turn for help. Another direct, but unfortunate, result of our past public health policy in this matter has been to promote higher fertility rates in that segment of the population which least wants and, from many viewpoints, should not have large families.

Attitude of the Public

Fortunately, in the past five years, public attitudes concerning contraception have changed radically, and discussion of every aspect of it has become part of the public dialog. For example, the Gallup Poll on January 6, 1965, reported that 81 per cent of the people interviewed favored making birth control information available anywhere in the United States to anyone who wants it. This was the largest percentage recorded and was largely due to the changing attitudes of the Catholic segment of the population. In June 1963, 53 per cent of Catholics interviewed said they believed birth control information should be available anywhere in the United States. In January 1965, 78 per cent held this view. This does not mean that

---

Continued

Catholics approved of all methods of birth control, but only that such help should be available for those who want it.

Religious Barrier

At the present time there is a rather remarkable consensus regarding contraception. For example, the major religious denominations agree:

1. On the objectives of family limitation; 2. On the general need for family limitation; 3. On the right of people to have help toward this end; 4. On the spending of public money for this purpose, with the important provisos that any such programs be voluntary, and that no one be advised to violate his religious convictions.

What controversy remains involves largely questions of methodology, and it is not inconceivable that even this remaining point of controversy can be largely mitigated, or removed entirely, by future developments. As a result of this rather widespread agreement, public health officials and government leaders are finally taking the necessary steps to make family planning services available to the disadvantaged portion of our society. More and more cities and states are setting up programs for this purpose. In Minnesota, public health programs for family planning have not been developed previously because of an 1886 law which classified all contraceptives as obscene materials and therefore illegal.* It is hoped that the present legislature will eliminate this archaic law so that the various state and county agencies can implement programs that have already been proposed.

Contraceptive Methodology

As noted above, there has been a revolutionary change in the contraceptive methodology. There can be no doubt that the discovery of the oral contraceptives has been one of the most important advances in this field. In addition, their use has been responsible, at least in part, for the changing public attitudes noted above. More recently, the perfection of the intrauterine contraceptive devices has added still another dimension in contraceptive technology.

The Ideal

In spite of these advances, the ideal contraceptive is still not at hand. Such contraceptive technique should meet the following criteria:

1. It must be reliable.
2. It must be simple to use.
3. It should be free of undesirable or deleterious side effects.
4. It should be inexpensive.
5. It should be reversible.
6. It should be acceptable to people of all cultures and religious beliefs.
7. It should require minimum motivation.

All of the above criteria are self-indicative except for the factor of reliability. Obviously any technique must have a certain level of effectiveness in order to be acceptable. The exact level of this reliability varies according to individual needs and preferences from being absolute and permanent to only partial and temporary.

Pearl's Formula

The most commonly used measure of effectiveness is still Pearl's formula where

$$R = \frac{\text{Total number of conceptions x 1200}}{\text{Total months of exposure}}$$

This formula is not precise because of a selection factor which tends to make failure rates decline as the period of contraceptive use increases. There have been a number of attempts to overcome this objection, but as yet the application of sophisticated statistical techniques for the comparison of contraceptive practices of the general population has not met with success. It has been calculated that R would have a value of approximately 80 in a so-called normal, uncontrolled exposure for American couples. However, this figure has been estimated to be as high as 120 in certain Central and South American countries. In a perfect contraceptive, R would be 0. Reliability should also be evaluated in terms of its use-effectiveness rather than its theoretical effectiveness. A method may be close to zero in failure rate in the laboratory or when perfectly applied. However, due to

a host of factors, this same technique may have a significant failure rate when used by the population at large.

The Reliability of Methods

Table 1 is a comparison of the various methods in use throughout the world with respect to some of the factors mentioned above. It will be noted that there is just as much variation in reliability with the same method as there is with different methods. This observation emphasizes the fact that the success of any method depends on multiple inter-related factors such as natural fertility, educational status and intelligence, economic level, religious bias, and many other cultural influences. In more concrete terms, it should be fairly obvious that while a given technique may be eminently satisfactory in the high income, high education Crocus Hill district of St. Paul, it may not be successful in the Selby-Dale area.

Table 2 is from the data of Westoff et al.[1] and is based on an analysis of 1,165 couples living in seven of the largest cities and their suburbs who were interviewed in 1957 about six months after the birth of their second child. This table gives us an estimate not only of the choice of methods in general use before the introduction of oral contraceptives, but also of their use-effectiveness. It points out that for all methods combined there was an average failure rate of 22.4 per 100 woman years. We can conclude from this that urban Americans were using birth control techniques quite effectively. Moreover, on re-interview three years later, it was found that those couples who had completed their families had a failure rate of only 3.7 per 100 years for all methods combined. This result points out the other single most important consideration in the application and use-effectiveness of these contraceptive methods — the factor of motivation.

TABLE 2
Months of Use of Contraception, Accidental Pregnancies, and
Failure Rate Per 100 Years of Use, by Method:
USA Metropolitan Areas*

Method	Months of Use		Accidental Pregnancies	Failure Rate
	No.	Per cent		
Condom	10,062	35.2	116	13.8

Continued

Motivated couples can use the more complicated techniques of diaphragm and jelly with almost perfect success. Likewise Tietze[2] has shown that the rhythm method can be made to be reasonably reliable in couples that are sufficiently motivated and under medical supervision.

Any successful approach to family planning for indigent and semi-indigent patients should give a proper emphasis to the above factors. It has been widely assumed that one of the reasons for the higher fertility of the indigent patients has been their lack of motivation. However, the studies of Rainwater[3] have pointed out the relationship of motivation to the total cultural setting of the indigent family. Numerous reports have documented the fact that the low-income, low-education status patient can use the oral contraceptives very successfully. Whatever the merits of the above reason, there is documentation for the following conclusions:[4,5]

1. Lower income families want smaller families on the average than high income families.
2. Nonwhites want smaller families than whites.
3. The overwhelming majority of indigent and semi-indigent desire help in family planning.
4. The less educated tend to use relatively less reliable methods of contraception than the more educated.
5. While the indigent patient may have less motivation than his upper-class counterpart, there is evidence that this lack, at least in part, is due to the conditions under which he has in the past received whatever contraceptive help was available.

Our experience at Ancker, which admittedly is recent and on a rather small scale, tends to corroborate the above observations. For example, 300 consecutive patients who were married and living with their husbands were interviewed on the post-partum ward. Of the total group, only 14 per cent stated that they had been trying to get pregnant. However, of those who had four or more children at home, only 2 per cent had been trying to get pregnant, and most of these gave as their reason the desire of a second husband to have children. Approximately 70 per cent stated that they had been attempting some form of birth control, including rhythm. It was evident, however, that in a majority of the patients contraception was applied either intermittently or haphazardly. It was particularly evident that many of the couples using the rhythm method had not been under medical supervision and were, in fact, using the method in such a manner as to actually hasten a pregnancy. Although almost 90 per cent of the patients stated that they now wanted help to prevent the next pregnancy, most of them had reservations about the methods they had used or heard about in the past. If, however, the time were taken to explain the various methods, most of their objections could be answered to their satisfaction. It came out during these interviews that there were marked individual preferences as to their choice of contraceptive methods.

On the basis of these preliminary inquiries, a more comprehensive program of family planning was started at Ancker Hospital. In addition to offering the oral contraceptives, a rhythm clinic was initiated. Also, one vaginal foam was added; and an intrauterine device is being inserted in carefully selected patients. As soon as funds become available, all reliable methods will be offered, and in cooperation with other agencies, evening clinics may be considered to make them more accessible.

This program has been in operation for less than a year and no data can be reported as yet. The initial response to family planning by the indigent patient has been excellent. It has also become clear that for persistent use of a contraceptive method, good rapport with the patient and sufficient personnel for thorough followup are essential. The acceptance and results of the various methods will be the subject of a subsequent report.

Summary

Family planning has become an accepted function of public health agencies and facilities. Such programs should take into account the diverse personal, religious, and cultural backgrounds of the low-income patient, and

offer a comprehensive program to suit individual needs. Preliminary evidence indicates that such a program could be successfully applied to nearly all patients.

Paleopathology V*: Peruvian

Examination of Pre-Columbian Peruvian mummies reveals that the early inhabitants of Peru, unlike the ancient Egyptians, were relatively free of two major pathologies: arthridites and arteriosclerosis. Since preservation by embalming was not an early Peruvian practice or ritual, most of the corpses were eviscerated and dried previous to wrapping, thus confining examination to the bone structure.

Tumors, it appears, were numerous — especially hyperostoses cranii, due to an endocranial tumorous condition of the dural membrane. Also prevalent were ivory-like osteomae on mummy skulls and mandibles.

As for oral diseases: whereas caries did not appear to be a problem, pyorrhea due to heavy calculus deposits was very common and doubtless the main cause of the edentia so frequently noted in these mummies.

Infant mortality must have been phenomenally high in ancient Peru, as indicated by an abundance of infant mummies in the Field Museum collection, most of them young children — either full-term or under two years of age. A puzzling question is: why did these infants die? The cause or causes are not apparent on the mummy remains and cannot be determined by roentgenographic examination.

In contrast with an incidence of 40-per-cent morbidity in Egyptian mummies, 53 Peruvian mummies revealed a significantly lower incidence of 10.52 per cent.

Why the striking differences between the ancient Egyptians and the Pre-Columbian Peruvians? Were climate and diet determining factors in the relative frequency or rarity of various diseases? What other influences may have been operative? These are some of the intriguing questions future paleopathologists will doubtless answer.

The Stethoscope Song

There was a young man in Boston town,
He bought him a stethoscope nice and new,
All mounted and finished and polished down,
With an ivory cap and a stopper too.

It happened a spider within did crawl,
And spun him a web of ample size,
Wherein there chanced one day to fall
A couple of very imprudent flies.

The first was a bottle-fly, big and blue,
The second was smaller, and thin and long;
So there was a concert between the two,
Like an octave flute and a tavern gong.

Now being from Paris but recently,
This fine young man would show his skill;
And so they gave him his hand to try,
A hospital patient extremely ill.

Some said that his *liver* was short of *bile*,
And some that his *heart* was over size,
While some kept arguing, all the while,
He was crammed with *tubercles* up to his eyes.

This fine young man then up stepped he,
And all the doctors made a pause;
Said he, The man must die, you see,
By the fifty-seventh of Louis's laws.

* * *

Then out his stethoscope he took,
And on it placed his curious ear;
Mon Dieu! said he, with a knowing look,
Why, here is a sound that's mighty queer!

The *bourdonnement* is very clear, —
Amphoric buzzing, as I'm alive!
Five doctors took their turn to hear;
Amphoric buzzing, said all the five.

There's *empyema* beyond a doubt;
We'll plunge a trocar in his side.
The diagnosis was made out, —
They tapped the patient; so he died.

* * *

Now use your ears, all you that can,
But don't forget to mind your eyes,
Or you may be cheated, like this young man,
By a couple of silly, abnormal flies.

Oliver Wendell Holmes

Medicine and Religion

The Dimensions of Medicine*

ORVILLE S. WALTERS, M.D.**
Urbana, Illinois

EVERY DOCTOR likes to think of himself as something of a scientist. The practice of medicine, like scientific research, calls for accurate observation, logical thinking and objective evaluation. In the course of his training, the physician has had some indoctrination in these disciplines. He has been required to master a considerable body of knowledge, the preclinical sciences, before he begins to work with patients.

Most young doctors, when their training is over, are eager to pit their new knowledge and skill against disease in the practice of medicine. A few, however, attracted by the still unexplored reaches of medicine, elect to remain in medical research. The driving curiosity that is an essential for every research scientist may overcome an urge to practice that is based upon the practical rewards of medicine and the opportunities for service that it brings.

The ultimate value of choosing medical research as a career may be greater than choosing medical practice. If the medical scientist is able to accomplish a break-through in some important area, or even to help lay the groundwork for some important discovery, he may become a greater benefactor to humanity than he could ever be as a practicing physician. Not every medical scientist can make the contribution of a Salk or a Fleming, but fortunately, many dedicated medical people continue to elect research careers.

The area of pure research may be looked upon as the scientific dimension of medicine. This devotion to an investigative career in some basic medical science has led to discovery of the antibiotics, the conquest of diabetes and pernicious anemia, the understanding of genetic disease, and the vast benefits of immunization.

While some few elect medical research, a far greater number of young physicians are eager to slay the dragons of disease and move directly into practice. This is the therapeutic dimension of medicine, where emphasis is upon treatment that will lead to healing. With a grounding in the basic sciences of physiology, pathology and pharmacology, the physician mobilizes every resource of knowledge and skill to heal his patients.

Analytical Thinking

When he meets a sick patient, the doctor's mind operates like a computer. The patient's complaint triggers a process of analytical thinking that almost automatically produces in the doctor's mind a list of possibilities, arranged in the order of statistical probability, even before he begins his examination. If the symptom is a pain in the right lower quadrant, appendicitis will probably be at the top of the list; ureteral stone and mittelschmerz will be somewhere in the middle, and ruptured ectopic pregnancy may be near the bottom. Then begins the clinical search, in which careful observation and clinical acumen eliminate one by one all the possibilities except the correct one. If the symptom is a high fever, an entirely different mental check-off list appears, with pneumonia, septicemia and numerous names ending in *itis* suggesting themselves as possibilities. Again,

Continued

*Presented at the 112th Annual Meeting of the Minnesota State Medical Association, May 17, 1965, Minneapolis, Minnesota.

**Director of University of Illinois.

the training, experience and astuteness of the physician will complete the process of elimination and diagnosis.

A physician's scientific training will not allow him to be content with treating the symptom and neglecting its cause. A common drug might relieve the abdominal pain or reduce the temperature, but the cause of the symptom would remain untouched. Only if the symptom can be traced to its origin can the cause of the illness be abolished. Modern medicine will never be satisfied with "symptomatic treatment," until every effort has been made to discover and eliminate the fundamental cause.

Psychosomatic Evaluation

If the chief symptom is emotional rather than physical, the diagnostic process is switched into an entirely different channel. Anxiety or depression shifts the search into the dimension of personality, for these signs indicate that the cause is broader and deeper than merely physical. In the therapeutic dimension, the physician sees a disease that needs treatment. In the dimension of personality, the patient must be seen as a whole person. This involves evaluation of the emotional and intellectual elements of personality — that is, how the patient feels and what he thinks, as well as his physiology — how his body works.

Disturbances of thought and feeling have long been considered the province of the psychiatrist. The regular physician often feels ill at ease in dealing with such disorders and may be inclined to refer his patient. While the psychiatrist is more closely concerned with the dimension of personality in his work, the rise of psychosomatic medicine has made it clear that no physician can avoid involvement in the emotional problems of his patients. He is the first to encounter these emotional problems. His patient may or may not be willing to consult a psychiatrist.

The dimension of personality also calls to mind a diagnostic check-off list, but one less precise than that for physical illness, and the process of elimination is far more complex. Since anxiety, like pain or fever, is only a symptom of deeper psychic conflict, the common causes of such internal discord must be passed in review, ranked according to their frequency.

The experience of the psychiatrist indicates that interpersonal conflicts will be at the top of such a list. The specific persons most often implicated are members of the family, such as parents, siblings or spouse. A second common cause of anxiety is some form of value conflict, in which the person has violated some system of values or moral standard. A third cause of conflict is a faulty personality pattern acquired in the developmental period. Over-aggressiveness and hostility, excessive dependency or pathologic seclusiveness may be causing the patient psychic "pain," impairing his relationships with other persons, and producing alienation.

What makes the dimension of personality more complex is that neurosis is a form of self-deception; hence, the patient usually does not understand his own disorder. The information he offers in the diagnostic search may be useless or even misleading. An important part of the treatment is to help him understand himself better and to reorganize his defective attitudes.

Psychotherapy

The underlying cause of most neurotic and personality disorders will be one of the following: (1) faulty interpersonal attitude, (2) warped attitude toward oneself, (3) value conflict, (4) developmental disorder of personality. Behind each of these is a disturbance in intellectual and emotional attitudes that the patient must be helped to understand and correct. This process of review by doctor and patient is called psychotherapy.

The physician may be tempted, when he encounters anxiety or depression in his patient, to prescribe a tranquilizer or an antidepressant drug without pursuing the diagnostic process further. But symptomatic treatment is no more respectable in the dimension of personality than it is in the treatment of physical illness. Scientific medicine demands that the symptom be traced to its cause, so that the cause may be eradicated.

Psychiatry is still young and is not yet solidly undergirded by a comprehensive psychology in the way that medicine is supported by its basic sciences. Psychology and psychiatry are splintered into numerous sectarian divisions, much as medicine proper was fifty years ago. The physician no longer has to choose whether he will be a homeopath, an eclectic or an allopath. The sects have disappeared as one stable scientific medicine has emerged. The multiplicity of psychologies may similarly be expected to merge into one scientific system as understanding of human personality grows.

Even then, psychiatry can never become wholly scientific, and the psychiatrist must always be more than a scientist. Many neurotic symptoms are traceable to warped attitudes, closely related to the system of values held by the patient. He may suffer, for example, from a sense of guilt, believing that he has done wrong. Science cannot tell him what is right and wrong; this is the province of ethics, a branch of philosophy.

A man may believe that God created the world, a proposition that science can neither affirm nor deny. His belief is an affirmation of faith, a philosophic postulate. Since the patient's beliefs may powerfully influence personality for good or ill, they must be understood and taken into account in treating the whole patient.

The Philosophical Approach in Medicine

The physician is likely to feel very uncomfortable in the realm of philosophy, which may seem to violate his training and cut him adrift from the sciences. A little reflection, however, will make him realize that he has always been dealing with philosophy, just as he has always been "talking prose." Every scientific hypothesis is first a theoretical conjecture. Even when completely corroborated by factual observation, science is underlain by philosophical assumptions about the uniformity of nature and how we may know it. Every simple act of daily living has ethical overtones which are rooted in some basic belief about the nature of man, the existence of God, and their ultimate relationship. These questions may not be as prominent when one is removing a gallbladder or pinning a hip as they are in anxiety or depression; but since they profoundly influence the whole man, they involve every patient and every physician to some degree. Anxiety, depression and personality disorder lead to disturbed attitudes and relationships, which cannot be understood without sharing some understanding of the patient's philosophy of life.

The Judeo-Christian faith is a complete philosophical system that encompasses man's origin and destiny, and that offers an ethical basis for living. Other systems of thought have developed with the coming of the scientific era, but they, too, are only competing philosophies with nothing more than modernity by which to claim superiority.

The Spiritual Dimension

There is still another dimension that the physician must recognize as he seeks to understand and heal the whole man. This is the spiritual dimension.

The Judeo-Christian faith offers not only a philosophy of history and an ethical system, but it tells of a divine-human encounter that has resolved guilt and given new meaning and purpose to existence, and that is open to universal replication. This encounter is an experience, not an intellectual construct. It is an element of existence rather than of philosophy. Such an experience is described by a contemporary in these words:

> More than ever before I am convinced of the reality of a personal God. True, I have always believed in the personality of God. But in the past, the idea of a personal God was little more than a metaphysical category that I found theologically and philosophically satisfying. Now it is a living reality that has been validated in the experiences of everyday life. (King, M. L. "Strength to Love," Harper & Row, 1964. Page 139.)

This experience has been reported by multitudes of persons through many centuries to be an antidote to the futility and meaninglessness of life and to the anxiety of death, and hence has had healing benefit. Any measure with such impressive claims deserves the attention of the physician, who increasingly has had to recognize the baneful effects of anxiety in his patients.

Religion has long been concerned with the spirit. The clergyman has been the specialist

Continued

in this dimension. When the physician concerns himself with his patient's value conflicts and their spiritual experiences, he will find the theologian has already been there a long time. The Judeo-Christian theology not only has a doctrine of man but has ministered to his spiritual needs for centuries. The growing recognition that spiritual problems can produce physical maladies gives new importance to collaboration between clergymen and physicians. Mutual confidence has been slow in developing, especially in the ranks of psychiatry, although the parish minister and the family physician have always been fairly close to each other because they have been close to their people.

The concept of dealing with the whole man not only involves the physician in the philosophic and spiritual dimensions, but it broadens the work of the clergyman as well, bringing him into a closer working relationship with the doctor. In this growing collaboration, the understanding of each can be enlarged. In this cooperation the patient becomes the ultimate beneficiary.

John Wesley had a remarkable insight into this understanding when he wrote these words two hundred years ago:

> Reflecting today on the case of a poor woman who had continual pains in her stomach, I could not but remark the inexcusable negligence of most physicians in cases of this nature. They prescribe drug upon drug without knowing a jot of the matter concerning the root of the disorder and without knowing this, they cannot cure, though they can murder the patient. Whence came this woman's pain (which she would never have told had she never been questioned about it) — from fretting for the death of her son. And what availed medicines while that fretting continued? Why then do not all physicians consider how far bodily disorders are caused or influenced by the mind and in those cases which are utterly out of their sphere call in the assistance of a minister; as ministers when they find the mind disordered by the body call in the assistance of a physician?
> (Wesley Journal, May 12, 1759, IV, 313)

Ladder of Hermes

The Ladder of Hermes was a preparation contrived by Gilbert of England in the thirteenth century. It consisted of 60 simples, compounded by arithmetic progression into one all-purpose prescription: One ounce each of four simples plus two ounces each of four more simples plus three ounces each of four more, etc., until all were incorporated into the final product.

This 15-step Ladder of Hermes was reputed to possess phenomenal potency in curing more than just 15 diseases!

Suspended Animation

The simplest form of suspended animation is that of fainting. When, from the effects of heat or of exertion combined with tight lacing, a young lady becomes pale, and falls down insensible and appears scarcely to breathe, the use of smelling salts is occasionally of service. Though a fainting fit is only the prelude to a fit of hysterics, the patient should be thoroughly roused, and a brisk walk between two not too sympathetic friends will then probably avert a domestic catastrophe.

A wise man sees as much as he ought, not as much as he can. — Montaigne

History of Medicine

Avicenna, The Prince of Physicians*

RAYMOND D. CLEMENTS, Ph.D.**
Bethesda, Maryland

Medically speaking the most influential of the medieval Arabian physicians in the West, Avicenna presents the paradox of being the most widely discussed but the least studied at first hand. He has been called everything from a professional scribbler whose works are a bundle of inanity to the Prince of Physicians. The one safe thing which we can say about him is that he was indeed influential from the 12th to the 17th centuries in Europe, that he transmitted to the West much of the medical theory and practice of the ancient physicians, and that he is still today reverenced as an authority in certain sections of Islam.

A typical, popular biography identifies him as a precocious, 10th century, Persian 'boy-wonder' who mastered metaphysics and logic by his sixteenth year, and who had a renowned reputation in medicine by his eighteenth year. In his adult life, he is typified as a happy-go-lucky, drunken rake in the early hours of the evening, reviving his mental faculties with wine, then meditating in a mosque, indefatigably working on affairs of state all day — all the while grinding out some hundreds of books on everything from medicine to philosophy and psychology. It is said, finally, that he died at the age of 58 of excesses.† If the stories are true, it would be even more remarkable that he could have escaped 'cirrhosis of the brain' long enough to write such an obvious exercise in sustained reasoning as his *Canon of Medicine.* For, whatever else it may be, the *Canon* does have that attribute.

As a physician, Avicenna proposed to deal with two aspects of medicine, the 'speculative' and the 'practical.' He felt that anyone planning to follow his teachings should commit them to memory, even without completely understanding the reasons behind them. He denied that medicine was a 'pure science' or 'speculative only,' and noted that every science has both a speculative and a practical aspect. This division he developed within the traditional Aristotelian distinction between 'potentiality' and 'actuality.' Very much in the same vein as Galen in the *Natural Faculties,* he then noted that the physician should not concern himself with metaphysical questions; but he himself subsequently disregarded the advice by discussing the four traditional elements making up the composition of man, namely: earth, water, air and fire.

Concept of Temperaments

In his concept of temperaments, Avicenna defined them in a manner reminiscent of Galen. Temperament was envisioned as that quality which resulted from the mutual interaction of the four contrary, primary qualities residing within the elements. Temperament was decided by the bal-

Continued

ance of these qualities. After offering eight varieties of temperaments, Avicenna considered the intemperaments, which we might cautiously label 'dyscrasia.' These, in turn, were simple or compound. Each organ or member of the body also had its own temperament, as well as each age, sex, geographical position and occupation. As evolved by Avicenna, these qualities were subdivided into an exhausting number of degrees.

The Humors

His concept of the humors was essentially Galen's. Healthy humor was that moist substance which replaced the loss which the body substance underwent. The residue, or superfluity, was called unhealthy humor. There were four body fluids or humors, namely: sanguineous or hot-moist; serous or cold-moist; bilious or hot-dry; and atrabilious or cold-dry. These, in turn, could be normal or abnormal in varying degrees. Avicenna felt that Galen was wrong in holding all the humors but blood as superfluities; but the reasoning for his disagreement with Galen was purely dialectical, e. g., if the serous humor did not nourish the brain, the brain would not be soft.

History of Medicine in Wright County*

As mentioned **Dr. F. A. Atwater** was the first resident dentist to locate in Wright County. He appears first in the Wright County newspapers in June, 1879. However, at first he is mentioned not as a resident dentist but because of his activities as delegate to the National Greenback State Conventions at St. Paul and for his activities as examiner and surveyor of land in the Red River and Northern Pacific Country. In December 1879 he resided at Long Lake but soon after that we find his card in The Eagle of Delano announcing him as "Resident Dentist. Office one door east of the Eagle office . . . Delano." Dentistry apparently did not provide a living as he also ran a clothing store. His store advertisements in the Eagle ended with the following notice: "N. B. Those wishing their teeth filled or extracted will also find my dental chair in readiness in the same place." It seems he experimented with tooth transplantation because in May, 1880 a news item tells that "Dr. Atwater supplanted another tooth this week after it had been extracted." As the year went on, his business affairs seemed to outweigh dentistry. In July, 1880 he became Justice of the Peace of Delano and his wife advertised her readiness to take in boarders; both indicate that extra earnings were needed. Soon he also became an agent for the Manhatten Insurance Company. In September, 1880 he purchased the Clerk House in Minneapolis and left Delano. He kept the Clerk House only eight or nine months, sold it at a good profit and moved with his family to Australia. It cannot be said that he enhanced the dental profession in Wright County. His newspaper ads apparently had the right appeal to the rural areas — they showed a picture of a man greatly suffering from an abscessed tooth.

Social Security for Doctors

Under the social security amendments of 1965, physicians and surgeons are brought into the system effective January 1, 1965. Those whose taxable years end on December 31 will pay the required tax on 1965 earnings by April 15, 1966, and annually thereafter by April 15 on their previous year's earnings.

Social security benefits are intended to be a partial replacement of earnings lost because of the worker's retirement, disability, or death. Only income from employment or self-employment counts as earnings under social security. Income from interest, dividends, rentals, sales of property, securities, etc. does not constitute earnings under the social security retirement test.

To be insured under social security and thus qualified for benefits upon retirement requires coverage for a certain minimum number of calendar quarters, depending upon sex and year of birth.

A male doctor born in the year 1897, now 68 years of age, requires 11 quarters of coverage; one born in 1900, now 65 years of age, requires 14 quarters of coverage; one born in 1915, now 50 years of age, requires 29 quarters of coverage; one born in 1935, now 30 years of age, requires 40 quarters of coverage. The intervening ages require comparable quarters of coverage.

Test for Retirement Benefits

Provisions under the retirement test beginning in 1966 include the following: An individual who is otherwise eligible will receive all of his social security benefits if he does not have earnings of more than $1500 in a taxable year. If he earns more than $1500 he loses $1 in benefits for each $2 earned above $1500, but not over $2700. He loses $1 in benefits for each $1 earned over $2700. Upon attaining the age of 72 he can earn all he wishes and still collect all of his social security benefits. Most doctors would earn too much to collect benefits before attaining that age.

A self-employed individual when eligible can receive social security benefits for any month in which he does not engage in a substantial amount of work in his profession or business, regardless of the amount of his annual earnings. As a guide, a self-employed person who works more than 45 hours in a month will be considered to be rendering a substantial amount of service. If he works 45 hours or less, he may be considered retired, depending upon the nature of his profession and the services rendered. If he works 15 hours or less a month, he will always be considered retired and eligible for payment for any such month. Therefore, any doctor eligible for benefits who does not work more than 45 hours in a calendar month should consult the nearest social security office to obtain an evaluation of his social security status.

Whenever benefits are suspended or reduced by reason of excess earnings, benefits to the wife are also suspended or reduced in the same proportion.

Military service prior to the effective date of the social security act, January 1, 1937, is not counted in determining quarters of coverage. Later military service, between September 15, 1940 and December 31, 1956, may be counted under certain conditions, which may be ascertained from the social security office. Active military service performed after 1956 is covered under Social Security. Earnings from military service will not dilute the average monthly earnings and thus reduce benefits, but in most cases doctors will not find their military service to be of any value by way of increasing their social security benefits.

Continued

However, some doctors who do not have enough coverage to be eligible for benefits may become insured by using credit for military service.

All doctors upon attaining age 65, including those who have not worked under Social Security, may apply at the nearest Social Security Office for hospital insurance benefits.

Tax Rates for Self-employed Doctors

The 1965 social security amendments provide tax rates and maximum taxes for all self-employed workers on earnings subject to the tax as follows:

PAYROLL TAX

	SELF-EMPLOYED WORKER	
	Tax Rate	Maximum Tax
1965 tax on first $4800 of yearly earnings	5.4 %	$259.20
Tax in future years — on first $6600 of yearly earnings:		
1966	6.15%	405.90
1967-68	6.40%	422.40
1969-72	7.10%	468.60
1973-75	7.55%	498.30
1976-79	7.60%	501.60
1980-86	7.70%	508.20
1987 and thereafter	7.80%	514.80

Monthly and Maximum Benefits

Assuming that the doctor earned $6600 annually from the first year of coverage beginning January 1, 1965, until retirement at age 65, or as soon thereafter as qualified, his monthly benefits would be approximately as follows:

Present Age	Qualifying Age	Monthly Benefit	Wife's Benefit	Total
68	71	$101.70 (sic)	$50.90	$152.60
65	69	96.30 (sic)	48.20	144.50
50	65	121.00	60.50	181.50
30	65	166.00	83.00	249.00

The male doctor born in 1897, now 68 years of age, could increase his social security benefits to a maximum by working as follows:

Through 1968	$122.00	$61.00	$183.00
Through 1969	143.00	71.50	214.50
Through 1970	163.00	81.50	244.50
Through 1971	168.00 (Max.)	84.00	252.00

A male self-employed doctor born in the year 1900, now 65 years of age, could increase the above monthly benefit of $96.30 by continuing to work beyond the minimum 14 quarters required for coverage. Assuming he continued to earn at least $6600 annually, his monthly benefits, with a possible maximum of $168.00, would be as follows:

	Monthly Benefit	Wife's Benefit	Total
Through 1969	$110.30	$55.15	$165.45
Through 1970	124.20	62.10	186.30
Through 1971	138.00	69.00	207.00
Through 1972	151.00	75.50	226.50
Through 1973	164.00	82.00	246.00
Through 1974	168.00 (Max.)	84.00	252.00

Maximum benefits for other ages which have not been detailed here can be obtained if the doctor works a few years beyond his sixty-fifth birthday. A table of details can be obtained from the social security office, but from the tables given in this manuscript a fairly adequate extrapolation would provide the figures.

In these illustrations only the 68, 65, and 50-year-old doctor can increase his benefits by continuing to work for a few years beyond his sixty-fifth birthday. The 30-year-old doctor, continuing to pay his social security tax, cannot appreciably increase his benefits after the age of 65, even though he continues to work and earn until the age of 72.

No doctor can collect his social security benefits and at the same time earn $6600 or more until he attains the age of 72, when he can then earn as much as he wishes and also collect the maximum social security.

Social Security vs. Life Annuity

It might be of some interest to compare the total monthly benefits for a 72-year-old married couple with the amounts obtainable from a commercial life annuity of similar type, if funds equal to the amount of social security taxes required under the present law could be accumulated in a savings account at 4 percent compounded annually, and invested at retirement in a life annuity. In this illustration income taxes on the savings account earnings have been ignored:

		Combined Monthly Annuity for Life No Principal Remaining		
	Funds Accumulated to Age 72	Social Security	Commercial Insurance	Life* Expectancy Age
From age 68	$ 1,704.00	$252.00	Nominal	81.08
From age 65	3,548.00	252.00	Nominal	80.01
From age 50	16,572.00	252.00	$136.40	76.23
From age 30	54,758.00	252.00	450.71	74.61

*American Table for 1949

The above annuities would be allocated between husband and wife at age 72 in the same proportion as the comparable social security benefits.

The 30-year-old doctor in the above table under the commercial annuity, for example, would receive a monthly life annuity of $300.47; his wife would receive one half of this amount while both were living, making a total of $450.71, and if she survived her husband her monthly annuity would be 82½ percent of his, or $247.89. Under social security she would receive $135.00 per month.

From these figures it is obvious that doctors older than 50 years of age can increase their social security benefits by continuing to earn and to pay the social security tax until maximum benefits are attained.

The 30-year-old doctor would come out about even if he retired at age 65. If he continued to work until age 72, earning $6600 a year and thus receiving no social security benefits until then, he and his wife would have to live to the age of 90 to recover in benefits, at the maximum rate of $252.00 per month, his social security contributions of $54,758. On a commercial life annuity at age 72, however, he and his wife could live out their lives handsomely on $450.71 a month as long as they live, with a life expectancy to 82.7 years.

The Advantages of Social Security

It provides an annuity for a doctor now older than 50 who at age 72 can receive greater benefits than from a comparable amount of saved income. In addition, it permits a doctor to retire as early as age 62 with a reduced benefit.

It provides hospitalization for doctors age 65 or older. It provides disability benefits if a doctor becomes unable to work before age 65. It also provides survivors' benefits to a doctor's widow and to his children if they are still young, up to a maximum of $368.00 a month.

For the doctor now 30 years of age it provides in effect an enforced savings comparable to a life annuity at age 65 from a commercial insurance company, if he continues to earn $6600 and receives no benefits until age 72.

Disadvantages of Medicare

For the doctor who has the ability to save consistently from the beginning of his career until age 65 or later, it's not a bargain.

It does not provide adequately for catastrophic medical or surgical illness.

Social security taxes and benefits in the above illustrations are those provided under the social security amendments of 1965. If the past is any guide to the future, however, it is highly probable that both the taxes and the benefits will be increased with the passage of time. What the 30-year-old doctor may be spending for and receiving from social security 40 years hence remains to be seen.

The figures on savings account accumulations and on life annuities were obtained from the Northwestern Life Insurance Company. The figures on social security taxes and benefits were provided by the local social security office, which should be consulted for any detailed information desired.

Medicare Law Provisions, Benefits Outlined

Medicare, formerly known as H.R. 6675, is now Public Law 89-97 or the Social Security amendments of 1965. Having been passed by the House of Representatives and Senate and signed by the President, Medicare has become a matter of vital importance to the physician and his patient.

While the scope of Medicare has not yet begun to unfold and many questions still remain unanswered at this time, certain facts are definite. These have been summarized in a pamphlet "Your New Health Insurance" published by the United States Department of Health, Education and Welfare. Copies of this publication and an application card are

Continued

being mailed to everyone 65 or over who is eligible for Social Security benefits and to beneficiaries who will be 65 years of age soon. The mailing is expected to be completed by the middle of December, 1965.

Following is the text of "Your New Health Insurance" reprinted for your information.

Your New Health Insurance

The Social Security Amendments of 1965, which were signed into law by President Johnson on July 30, provide two different kinds of health insurance for people 65 or older.

- *Hospital Insurance,* which will pay most of the cost of hospital services and certain other posthospital expenses.
- *Medical Insurance,* which will help you pay much of the cost of doctors' services and certain other medical expenses.

Since you are 65 or will be before July 1966 and are entitled to social security or railroad retirement benefits, you will automatically be covered by the hospital insurance program. You will be covered by the medical insurance program only if you apply for it. In order to get this protection, you should fill in and return the enclosed card.

Important!

Do not because of this new law cancel any hospital insurance or medical insurance you may already have. The hospital insurance and medical insurance under the Social Security Act do not begin until July 1, 1966.

Your Hospital Insurance

All social security beneficiaries 65 or over are automatically entitled to *Hospital Insurance* benefits and need not take any action.

What Services Are Covered?

Beginning in July 1966, the hospital insurance program will pay the cost of covered services for the following hospital and posthospital care:

- Up to 60 days in a participating hospital (except for the first $40) and all but $10 per day for an additional 30 days for each spell of illness.* (There is a lifetime limit of 190 days for treatment in mental hospitals.)
- Up to 20 days in an extended care facility (a qualified skilled nursing home or a convalescent section of a hospital) and all but $5 per day for an additional 80 days for each spell of illness* You must have been in a hospital for at least 3 days before these benefits are payable. (This part of the program begins on January 1, 1967.)
- Up to 100 home-health visits by nurses or other health workers from qualified home health agencies (but not doctors) in the 365 days following your release from a hospital after a stay of 3 days or more, or from an extended care facility.
- 80% of the cost of outpatient diagnostic tests in a hospital (after you pay the first $20) for each 20-day period of diagnostic testing.

For services in a hospital or extended care facility, benefit payments will cover the cost of services in semi-private accommodations plus the cost of drugs, supplies, and most services customarily furnished by the institution.

What Services Are Not Covered?

No payment will be made under hospital insurance for the services of physicians, including the services of anesthesiologists, radiologists, physiatrists and pathologists. (The supplementary medical insurance program, however, does cover physicians' services). Payment will not be made for private duty nurses, custodial care, or for items furnished for the patient's convenience.

Payments will ordinarily be made under the program only in the 50 States, the Commonwealth of Puerto Rico, the Virgin Islands, Guam, and American Samoa. Hospital services under the basic hospital insurance plan may be provided in border areas immediately outside the United States if comparable services are not accessible in the United States for a beneficiary who becomes ill or is injured in this country.

Your Health Insurance Card

You will receive through the mail a health insurance card shortly before July 1, 1966.

When your doctor arranges for you to receive services covered by your hospital insurance, show your health insurance card to the hospital, extended care facility, or home health agency which is to provide the services. The hospital insurance program will pay for the covered services you receive as described on pages 2 and 3 of this leaflet. If you enroll in the medical insurance program described below, your health insurance card will show that you are also entitled to the services covered under that program.

---

*A "spell of illness" begins on the first day you receive covered services as a patient in a hospital or extended care facility. It ends after you have been out of a hospital or extended care facility for 60 consecutive days. You may be discharged and readmitted several times during a spell of illness, but a new spell of illness cannot begin until you have not been a patient in any hospital or extended care facility for 60 consecutive days.

Your Medical Insurance

Medical insurance is voluntary, with both you and the government sharing the cost equally. To get this insurance when the program begins, you must apply for it by March 31, 1966.* Please fill out and mail the card even if you do not want medical insurance, so that we may be sure that you have had an opportunity to consider the medical insurance plan. If you decide to take medical insurance, $3 a month will be deducted from your benefit checks beginning with the check you receive in July 1966. You do not pay any cash.

What Does Medical Insurance Cover?

Beginning in July 1966, the medical insurance program will help you pay for the following medical services:

- Physicians' and surgeons' services in the hospital, doctor's office, home, or elsewhere.
- Up to 100 home health visits under an approved plan each year with no need for prior hospitalization. This is in addition to the 100 visits provided under the hospital insurance program.
- A number of other medical and health services, such as diagnostic services, X-ray or other radiation treatments, surgical dressings and splints, casts, and rental of medical equipment.

Does Medical Insurance Pay the Full Cost of These Services?

No. You pay the first $50 in each calendar year for these services. Your medical insurance then pays 80% of the reasonable charges** for additional services. For example, if your covered medical bills were $500 in a year, the program would pay $360. Your medical insurance pays only for services you receive beginning with July 1966. No expenses you have before that time can count toward the $50 you pay.

What Is Not Covered?

Medical insurance does not cover some services such as the cost of routine physical check-ups, drug prescriptions, eye glasses, hearing aids, and ordinary dental treatment. It does not cover services received outside the United States (except for Puerto Rico, the Virgin Islands, Guam, and American Samoa).

How Do You Pay for Medical Insurance?

If you are receiving social security payments, you will not pay any cash; your $3 premium will be deducted from your social security check beginning with the check you receive in July 1966 and your insurance will begin with that month.

If you are not eligible for social security checks for one or more months, you will be informed how to continue your insurance.

The law provides that the $3 premium rate will be continued through 1967.

In each odd-numbered year beginning with 1967, the cost of the medical insurance program will be studied. If the premium rate, including the government's share, is not enough to cover the cost of the program for the next two years, the rate may be changed. The government will continue to pay half the cost.

When you enroll for medical insurance, you are not under any obligation to continue it beyond the end of the next odd-numbered year. Thus, if there is at any time an increase in the premium rate, you will at the same time have an opportunity to drop out of the program if you wish.

If You Decide to Drop This Insurance

If your premiums are being deducted from your social security benefits and you decide to drop out of the medical insurance program, you may do so during the last quarter of any odd-numbered year.

If you do drop out, you may re-enroll once,

Continued

---

*If you will reach 65 in January 1966 or later, your first enrollment period will end 3 months after the month in which you reach 65.

**For services provided by an organization on a prepayment basis and for certain other services, the medical insurance may pay 80% of the reasonable cost rather than 80% of the reasonable charges.

but only during the last quarter of an odd-numbered year and only if you re-enroll within three years after you dropped out.

What You Will Lose If You Enroll Late

There are several good reasons for signing up for the medical insurance program during your first enrollment period. If you pass up your first opportunity, you will not have another chance to sign up until the next general enrollment period (October 1, 1967, to December 31, 1967). Furthermore, if you wait to enroll, you may have to pay a higher premium for the same protection; and your coverage will not begin until 6 to 9 months after you enroll.

These provisions take into account the higher cost of insuring a person who does not enroll and begin paying premiums at his first opportunity.

If You Cannot Meet Your Medical Expenses

The health insurance programs will pay a large part of the cost of health care for most older people, but they do not pay the entire bill. If you have medical expenses you cannot pay, you may qualify for aid from your public welfare agency. Most States have medical care programs for aged people who cannot pay their medical bills and the 1965 Amendments make it possible for the States to strengthen and improve these services. Your public welfare agency may be able to help you.

The Venous System in Ancient Egypt

In the Heart are the vessels to the whole of the body.

There are four vessels to the Nostrils, two of which convey mucus and two blood.

There are four vessels in the inside of either Temple.

There are four vessels which divide in the Head and spread out in the back thereof.

There are four vessels to his Ears, two to the Right side and two to the Left. Breath-of-Life goes in the Right Ear and Breath-of-Death into the Left.

There are six vessels that run to the Arms, three to the Right and three to the Left, and they lead right down to the Fingers.

There are six vessels that lead to the Feet, three to the Right and three to the Left. They reach down to the Soles of the Feet.

There are two vessels to his Testicles which convey the Semen. There are two vessels to the Kidneys, one to one Kidney, the other to the second Kidney.

There are four vessels to the Liver which convey to it Moisture and Air.

There are four vessels to the Intestines and to the Spleen which likewise convey Moisture and Air. There are two vessels to the Bladder which convey the Urine.

There are four vessels which end in the Rectum. They give and bring forth in it Moisture and Air. Afterwards they turn towards the Rectum, each vessel to the Right and Left side right down to the Feet, mixing itself with the excrement.*

Minnesota Heart Association and American College of Cardiology Symposium, December 4 (one day) at the Sheraton-Ritz Hotel in Minneapolis. Subject will be: "Adrenergic Blocking Agents with Special Reference to Hypertension and the Catecholamines." Contact: Executive Secretary of American College of Cardiology, 9650 Rockville Pike, Washington, D.C. or the Minnesota Heart Association Office in St. Paul.

The Pharmacopoeia of Ancient Egypt

A glance through the pharmacopoeia on which the Papyrus Ebers is based is not to be undertaken lightly. To be sure we encounter there a number of drugs that figure in our pharmacopoeia today, but they are dwarfed by the weird and wonderful substances that the Scribe gravely transcribes. It is here that we first make acquaintance with that God-given drug, Castor Oil, which besides finding itself in a hundred prescriptions has the honour of a special mention in the body of the book:

"*Memorandum on the Use of the Castor Oil Tree (As Found in the Ancient Writings of the Wise Men)*

When a Person rubs its Stalk in Water and applies it to a Head which is Diseased, he will immediately become as if he had never been ill.

When a Person who suffers from Constipation chews a little of its Berry along with Beer, then the Disease will be driven out of the Sick One's body.

Furthermore, the Oil from its Berries is pressed out as an Ointment for the use of any Person who has the uha-abscess-with-stinking-matter. Lo, the Evil will fly as though he had suffered nothing! For Ten Days he anoints himself afresh daily in the morning in order to drive the abscess away.

But extolled though it was these ancient physicians were not satisfied with Castor Oil alone, and in their search for the wherewithal to fight the disease which afflicted the land they reached as high as the heavens, actually prescribing Excrement-of-the-Gods. They laid heavy hands on the animal world, on the mineral world, on the plant world, and not least on the World of Fancy; and having got a substance which they imagined possessed the slightest therapeutic virtue they prescribed it internally and externally, raw and cooked, ripe and unripe; in some cases over-ripe and actually rotting.*

Their ingenuity not yet exhausted, they turned their attention to the administration of the remedies, exhibiting again a versatility in every way comparable to their pharmaceutical efforts. Thus, we read of the mother who was instructed to spit the remedy into the child's mouth, of the woman who was ordered to take her medicine while she sat cross-legged, and of that other lady who, after chanting the Magic Formula, was told to have coitus before swallowing the medicament.

A final reference must be made to the vehicles by which it was sought to make the nauseous mixtures and objectionable messes which passed for poultices less nauseous and less objectionable. These vehicles, Beer, Milk, and Water, were employed with well balanced impartiality; they were often to be found in the same concoction; they appear in all sorts of forms, recognizable and unrecognizable. Thus Beer, a favourite vehicle, was prescribed as Plain Beer, Sweet Beer, Bitter Beer, Cold Beer, Warmed Beer, Flat Beer, Yeast-of-Beer, Froth-of-Beer, Beer-which-has-been-Brewed-from-many-Ingredients; while in a bright moment they bethought themselves of Swill-of-Beer. Milk also afforded them some scope; it appears as Fresh Milk, Sour Milk, Spoiled Milk, Cooked Milk, Ass's Milk, Cow's Milk, Man's Milk, Milk-of-a-Woman, Milk-of-a-Woman-who-has-borne-a-Son, Milk-of-the-Sycamore, and Milk-juice. As for Water, we find Plain Water, Well Water, Spring Water, Salt Water, Mineral Water, Cake Water, Linseed Water, Natron Water, Water-from-the-Bird-Pond, Water-from-the-Rain-of-the-Heavens, and Water-in-which-the-Phallus-has-been-washed!"*

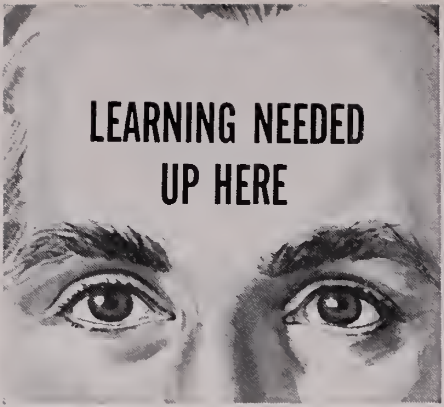
WANTED: Generalist desiring fast start in too busy St. Paul practice. No covenants or contingent clauses. You move to available nearby independent office facilities as soon as you establish an adequate following of your own, or you stay as a partner if you desire. Incidentally lousy working conditions: new building, built-in Hi-fi, every third week off. If you desire to establish yourself permanently in present location. You name your own terms. Write MINNESOTA MEDICINE — 336, 496 Lowry Medical Arts Building, St. Paul 55102.

Astrology and Medicine

In the broad and baffling spectrum of human maladies distant Uranus is responsible for such ailments as ruptures, strictures, cramps, and spasms — besides hallucinations and some other psychic disturbances. Neptune, still more remote from earth, is culpable for such obscure and unresponsive disorders as comas, hypochondriasis, somnambulism, and drug addiction. Both Uranus and Neptune have an aura of mystery and other-dimensionalism.

Democracy is based upon the conviction that there are extraordinary possibilities in ordinary people. — H. E. Fosdick



Who will do it? The colleges of course! They educate leaders to meet the challenges America faces in business, science, government, everyday living.

But the colleges need help. Quality education is expensive, and more Americans require a college education.

College is America's best friend. Give to the college of your choice —keep our leaders coming.

THIS SPACE CONTRIBUTED BY THE PUBLISHER

Anturane®
brand of
sulfinpyrazone

Dosage
Anturane, brand of sulfinpyrazone, is available as white, scored tablets of 100 mg. Initially, give half a tablet 4 times daily with meals or milk, increasing in one week to one tablet q.i.d. Increase to two tablets q.i.d. if necessary, and reduce if possible to as low as half a tablet q.i.d. after control. Continue through acute attacks, which can be concomitantly treated with phenylbutazone.

Patients on other uricosurics may be transferred to this drug at full dosage.

Contraindications
Active peptic ulcer. Salicylates and citrates antagonize the drug's action and are contraindicated for concomitant use.

Warning
Use with caution in pregnant women.

Precautions
Keep patients under close supervision and make periodic blood counts. Use cautiously in patients sensitive to pyrazoles, in patients with histories of peptic ulcer, and in conjunction with sulfa drugs, the sulfonylurea hypoglycemic agents, and insulin, the actions of which may be potentiated.

In mobilizing urate deposits, the drug may precipitate acute attacks of gout, urolithiasis, and renal colic, especially in the initial stages of therapy. Ensure adequate fluid intake and alkalinize the urine. With renal impairment, test renal function periodically.

Adverse Reactions
The most frequent are upper gastrointestinal disturbances. The drug may activate peptic ulcer. Rash occurs infrequently. Although not reported to date, blood dyscrasias are a possibility.

Anturane®
brand of sulfinpyrazone

'the most effective and best tolerated of the currently available uricosuric agents for the control of gout.'*

Geigy

Anturane, brand of sulfinpyrazone, was developed in the Geigy laboratories. Its pharmacologic activity is limited almost exclusively to increasing the urinary excretion of uric acid. For this reason, it is a drug of choice in chronic tophaceous gout and acute intermittent gout. It is not intended for relief of acute attacks of gout.

In most patients, the drug rapidly reduces serum uric acid levels to normal. This not only prevents new tophi but also mobilizes and promotes the excretion of urates already in the tissues. The reduction of tophi and periarticular crystals results in more mobile, less painful joints.

Anturane, brand of sulfinpyrazone, materially reduces the number and severity of acute attacks of gout. It may also be used to counteract hyperuricemia induced by certain diuretics.

Because of its potency, the drug is often effective in patients refractory to other uricosuric agents. Patients can usually be maintained indefinitely on it without cumulative effects or development of tolerance.

*Kuzell, W. C., et al.: Effect of sulfinpyrazone on serum uric acid in gout: a long-term study, Geriatrics 19:894, 1964.

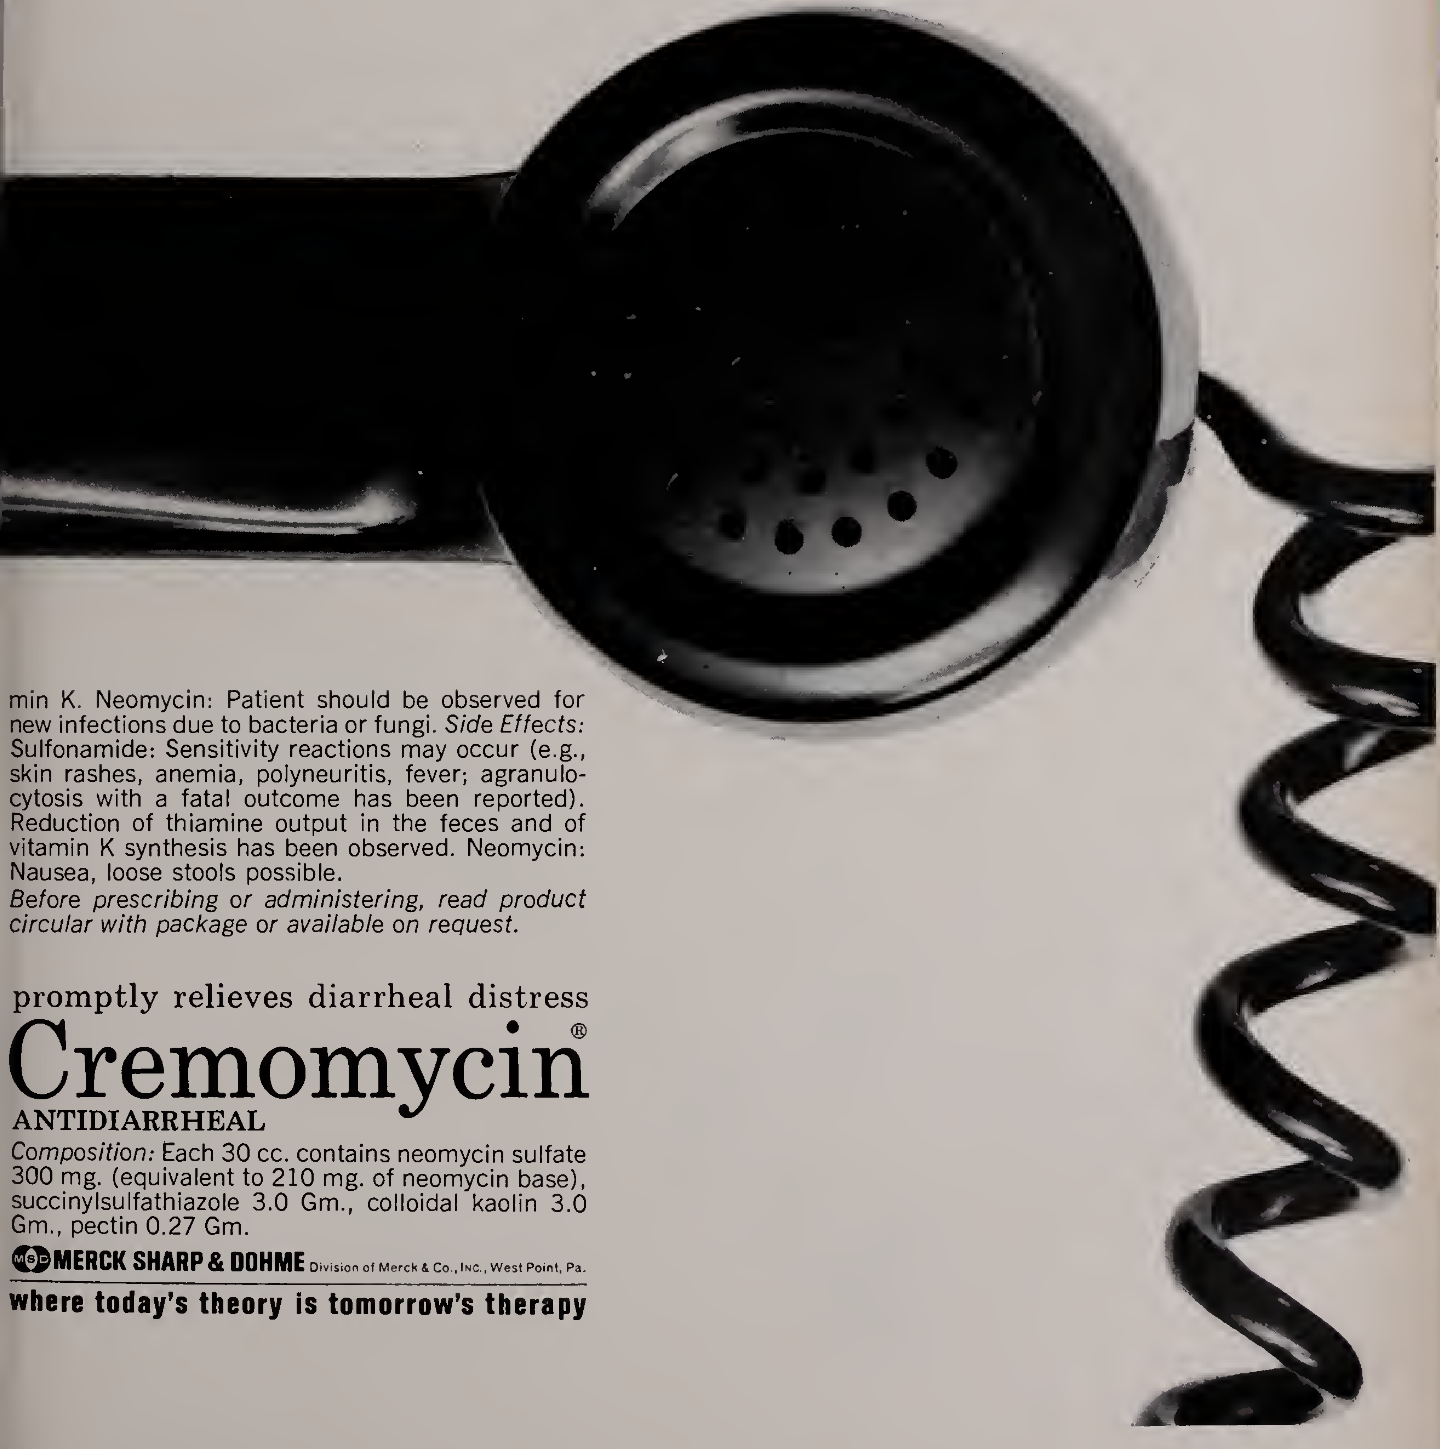
When uncontrolled diarrhea brings a call for help

When the diarrhea sufferer has run the gamut of home remedies without success, pleasant-tasting CREMOMYCIN can answer the call for help. It can be counted on to consolidate fluid stools, soothe intestinal inflammation, inhibit enteric pathogens, and detoxify putrefactive materials—usually within a few hours.

CREMOMYCIN combines the bacteriostatic agents, succinylsulfathiazole and neomycin, with the adsorbent and protective demulcents, kaolin and pectin, for comprehensive control of diarrhea.

Indications: Diarrhea. *Contraindications:* Kaolin: Withhold if diverticulosis is present or suspected. *Precautions:* Sulfonamide: Continued use requires supplementary administration of thiamine and vita-

your ℞ for Cremomycin can provide relief



min K. Neomycin: Patient should be observed for new infections due to bacteria or fungi. *Side Effects:* Sulfonamide: Sensitivity reactions may occur (e.g., skin rashes, anemia, polyneuritis, fever; agranulocytosis with a fatal outcome has been reported). Reduction of thiamine output in the feces and of vitamin K synthesis has been observed. Neomycin: Nausea, loose stools possible.

Before prescribing or administering, read product circular with package or available on request.

promptly relieves diarrheal distress

Composition: Each 30 cc. contains neomycin sulfate 300 mg. (equivalent to 210 mg. of neomycin base), succinylsulfathiazole 3.0 Gm., colloidal kaolin 3.0 Gm., pectin 0.27 Gm.

MSD MERCK SHARP & DOHME Division of Merck & Co., Inc., West Point, Pa.

where today's theory is tomorrow's therapy

"...it is extremely difficult and sometimes impossible to differentiate between 'pure depression' and anxiety and it is questionable whether depression without a certain degree of anxiety really exists."

Lehmann, H. E., Canad. Psychiat. Assn. J. *4(S)*: 1-12, 1959

anxiety
depression
anxiety
depression

An antidepressant designed for the clinical realities of office practice

As many physicians have reported, the large majority of neurotic depressed patients suffer from both depression and anxiety. It may be difficult to decide whether these patients are primarily depressed or primarily anxious. And yet drug treatment of only the symptom which seems more prominent may exacerbate the untreated element of the depression complex.

Consequently, it would seem that therapy specifically aimed at both the depression and associated anxiety and tension should increase success in treatment.

This is one of the important reasons why 'Deprol' has proved particularly helpful. For 'Deprol' acts rapidly both to lift the mood and to relieve the associated anxiety, tension and insomnia.

And side effects, at recommended dosage, have been infrequent and generally readily controlled.

Indications: 'Deprol' is useful in the management of depression, both acute (reactive) and chronic. It is particularly useful in the less severe depressions and where the depression is accompanied by anxiety, insomnia, agitation, or rumination. It is also useful for management of depression and associated anxiety accompanying or related to organic illnesses.

Contraindications: Benactyzine hydrochloride is contraindicated in glaucoma. Previous allergic or idiosyncratic reactions to meprobamate contraindicate subsequent use.

Precautions: *Meprobamate*–Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of pre-existing symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Side effects associated with recommended doses of 'Deprol' have been infrequent and usually easily controlled. These have included drowsiness and occasional dizziness, headache, infrequent skin rash, dryness of mouth, gastrointestinal symptoms, paresthesias, rare instances of syncope, and one case each of severe nervousness, loss of power of concentration, and withdrawal reaction (status epilepticus) after sudden discontinuation of excessive dosage.

Benactyzine hydrochloride—Benactyzine hydrochloride, particularly in high dosage, may produce dizziness, thought-blocking, a sense of depersonalization, aggravation of anxiety or disturbance of sleep patterns, and a subjective feeling of muscle relaxation, as well as anticholinergic effects such as blurred vision, dryness of mouth, or failure of visual accommodation. Other reported side effects have included gastric distress, allergic response, ataxia, and euphoria.

Meprobamate—Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Dosage: Usual starting dose, one tablet three or four times daily. May be increased gradually to six tablets daily and gradually reduced to maintenance levels upon establishment of relief. Doses above six tablets daily are not recommended even though higher doses have been used by some clinicians to control depression and in chronic psychotic patients.

Supplied: Light-pink, scored tablets, each containing meprobamate 400 mg. and benactyzine hydrochloride 1 mg.

Before prescribing, consult package circular. CD-5749

Hygroton®

brand of
chlorthalidone

the longest-acting diuretic

Indications: Many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.
Warning: With administration of enteric-coated potassium supplements, the possibility of small bowel lesions should be kept in mind.
Precautions: Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Side Effects: Agranulocytosis, constipation, dizziness, dysuria, headache, hyperglycemia, hyperuricemia, impotence, leukopenia, muscle cramps, nausea, postural hypotension, purpura, thrombocytopenia, transient myopia, urticaria, vomiting and weakness.
Average Dosage: One tablet (100 mg.) daily with breakfast.
Availability: Tablets of 100 mg. in bottles of 100 and 1000.
For full details, see the complete prescribing information.

good riddance

Hygroton, brand of chlorthalidone, gets rid of edema efficiently. Your edematous patients will generally need far fewer tablets than with most diuretics. And they'll generally save more on prescription costs. One tablet a day is a popular dosage. So is one tablet every other day. You may even find half a tablet three times a week does the job. No other diuretic works as long. And none has as much natruretic activity per tablet.* For good riddance of edema with the least number of tablets, prescribe Hygroton, brand of chlorthalidone.

Hygroton® brand of chlorthalidone Geigy

Minnesota Medicine at a Glance

Digitalis in Pediatric Patients, Lade Page 1425

Because a large majority of infants who develop congestive heart failure die in infancy, it is extremely necessary to be able to adequately diagnose and treat these infants in the early stages. The recognition of this condition and the details necessary in the treatment are lucidly described in this manuscript.

Gardner's Syndrome, Shook and Windschitl Page 1431

Gardner's syndrome of polyposis of the colon, osteomatosis, and soft tissue tumors sometimes referred to as Peutz-Jeghers syndrome, is considered to be a familial disorder probably due to a defective gene with a dominant mode of inheritance. A soft tissue tumor in the frontal sinus and multiple polypae in the colon are illustrated in this manuscript.

Gastrostomy Tube for Infants, Root Page 1433

The use of a Davol tube for gastrostomy in infants is well worth consideration as has been described in Dr. Root's manuscript. In the infant with congenital esophageal atresia, or some other disease in which gastrostomy is urgently indicated, it is pointed out that there are some hazards associated with the continuous pressure of other types of gastrostomy tubes which, because of lack of resilience, can cause pressure necrosis in the wall of the stomach.

Pseudocysts of the Pancreas, Perry and LaFave Page 1440

A pseudocyst of the pancreas can be an annoying type of disease. There have been a variety of surgical procedures designed to eliminate the cyst. Perry and LaFave have produced the best results with the use of a cystjejunostomy Roux-en-Y procedure.

Though one does not often encounter pancreatic cysts it is well to keep in mind the variety of procedures that are used for this condition. Therefore a review of this manuscript is of value.

Sickle Cell Disease, Shook and Windschitl Page 1445

Sickle cell disease occurs only in the Negro, and whenever hematuria is encountered in these individuals, sickle cell hemoglobinopathy should be suspected.

The hematuria associated with this condition almost always stops spontaneously; there is no specific treatment. Bed rest and transfusions as indicated seem to offer the best approach to this problem.

Unilateral Pulmonary Edema, Perlman Page 1450

Treponea is a clinical condition wherein breathing is comfortable in one position but not in another. A documented case report proving the presence of pulmonary edema on one side has been recorded by Perlman. This elderly patient responded to treatment by the administration of Digoxin and Mercurhydrin.

Seizures, Gumnit Page 1453

The chief problem facing a physician is to determine the cause of seizures, as many seizures are not what is commonly known as epilepsy. There are a considerable number of causative factors which are reversible, and there are also other types of seizures which require specific therapy. Without differentiating the various types of seizures one cannot intelligently treat a patient who is suffering from these symptoms. The cryptogenic seizures which form a large part of the epilepsy pattern are ideopathic in nature, though they do have a slight tendency to appear in families.

Papillary Muscle Dysfunction, Burns and Layman Page 1458

In ventricular systole the first area of the myocardium to contract are the two papillary muscles of the left ventricle. The increased pressure within the heart tends to balloon the mitral leaflet toward the atrium, but because of the firm anchor of the contracted papillary muscles, only the diaphragm of the leaflets moves, and the free edges being held within the ventricular cavity undergo a ballooning effect so as to cause a tight closure of the mitral valve. Infarction of these papillary muscles could cause disruption of the normal architecture and consequent episodes of mitral insufficiency, as observed in the case reported by Burns and Layman.

The Acutely Injured, Root Page 1497

The greatest mortality among the acutely injured patients occurs within the first few hours following injury, and it is therefore important that the dangers of mobilization, transportation and the importance of early treatment be well understood in an effort to diminish this high mortality.

At Ancker Hospital, before an acutely injured individual is extensively moved about, he is rapidly but meticulously evaluated because the loss of blood, the hypotension, and the possibility of cord transection all may be aggravated by careless mobilization.

If respiratory insufficiency is then observed it is immediately followed by treatment through the introduction of an open airway, or if pneumothorax is evident this complication receives priority as it is the least well tolerated and must be corrected before any of the other vital signs can be attended to. Until the vital signs are stabilized the patient is maintained immobilized until his clinical status can be fully evaluated.

Herniated Disc, Neurological Conference Page 1507

The low back pain scale is on occasion one of the helpful tests designed in connection with the Minnesota Multiphasic Personality Inventory test to differentiate between organic back pain and that type of back pain which could be a conversion reaction and hypochondriasis.

Intervertebral disc compression most commonly observed in the fifth lumbar nerve or in the first sacral nerve does provide some fairly definite clinical manifestation. An evaluation of this annoying and disabling back symptom is clearly detailed in the Neurological Conference.

School Failure — Jensen Page 1515

When a child begins to fail in school a vicious cycle may develop in which he recognizes his own inability to compete successfully. He senses the disappointment in his parents; he feels the loss of acceptance by his schoolmates. With this there is a change in his general behavior and he may develop a host of physical complaints which in turn provide excuse for repeated absences from school. The attitudes of the teacher, his parents, and his doctor can either help or hinder the proper adjustment process, which must be recognized early in order that remedial measures can be instituted.

Sudden Death, Edwards Page 1519

This pathologic description of sudden death is a classic. In order to obtain an awareness of the potential problems with which the clinician may be faced when he encounters sudden death, a review of this classic manuscript would be well worth the effort.

Carbon Monoxide Intoxication, Grand Rounds Page 1537

The average motor vehicle produces in its exhaust, 3.5% carbon monoxide and 11.5% carbon dioxide. The principal mode of action of carbon monoxide in the body is by a reversible combination with circulating hemoglobin. Its lethal effect is by way of blocking out the oxygen-carrying capacity of the hemoglobin, thereby causing anoxia.

As a driving hazard, carbon monoxide produces an effect on the eyes and, in addition, weakness to the muscles of the body. A blood carbon-monoxide level of 15% would be sufficient to cause the toxic symptoms. Treatment consists in the use of hyperbaric oxygen administration, mercury-vapor light and succinic acid.

Hemolytic Anemia and Open Heart Surgery, Green Page 1545

A new syndrome of hemolytic anemia is being observed following open heart surgery. Hemoglobinemia and hemoglobinuria occur almost routinely following extracorporeal circulation. This type of hemolytic anemia falls into two categories: that in which the mechanical factor alone appears to be responsible and an autoimmune state, the pathogenesis of which is not clear.

In those instances in which a mechanical abnormality is the sole producing factor, reoperation for correction of the mechanical defect is recommended. For that type in which antiglobulin tests are positive, a response to corticosteroids has been found satisfactory.

Family Planning, Hakanson Page 1557

Ignorance, political opposition, and religious prejudice have been the major deterrents to the sensible application of contraceptive methods, but these barriers are gradually being eliminated and with this, reliable methods for family planning become possible.

Physician's Diary

I am wealthy in my friends — Shakespeare

Dr. Edward S. Judd, head of a section of surgery in the Mayo Clinic, Rochester, and professor of surgery in the Mayo Graduate School of Medicine, received a Distinguished Alumnus Award from the Geisinger Medical Center at Danville, Pennsylvania.

* * *

Dr. William C. Bernstein, Director, Division of Proctology, University of Minnesota, was elected Vice President of the American Proctologic Society, at its annual meeting in Minneapolis, June 14th.

* * *

Dr. Louis A. Brunsting, senior consultant in dermatology in the Mayo Clinic, Rochester, and professor of dermatology in the Mayo Graduate School of Medicine, University of Minnesota at Rochester, gave the Fifth Paul A. O'Leary Memorial Lecture at the annual meeting of the Minnesota Dermatological Society at Rochester in September.

* * *

Dr. A. I. Arneson of Morris was named recipient of the WCCO Radio "Good Neighbor Award" in August.

* * *

Dr. Benjamin M. Tuma of the Family Medical Clinic in Montgomery, has been elected to active membership in the American Academy of General Practice.

* * *

Dr. A. S. Zelickson of Minneapolis, assistant professor of Dermatology at the University of Minnesota, was the guest speaker in a course of dermalpathology of the Skin and Cancer Hospital of Philadelphia, held September 27th through October 1st.

* * *

Dr. William H. Remine, head of a section of surgery in the Mayo Clinic, was elected president of the Minnesota Surgical Society at the annual meeting of the group at Duluth in July, and **Dr. Edmund C. Burke**, a consultant in pediatrics in the Mayo Clinic, was elected first vice president of the Southern Minnesota Medical Association at the group's annual meeting.

* * *

NEW LOCATIONS: **Dr. F. D. Banfield** has become associated with the Olmsted Medical Group . . . **Dr. Ray Magnuson** of Cambridge has left that town for Gendeberet, Ethiopia, where he will work in a leprosarium . . . **Dr. Earl H. Wood**, Mayo Clinic, will study for a year in the Physiology Institute at the University of Berne in Switzerland . . . **Dr. J . A. Stenzel** of Minneapolis has begun practicing medicine at the new Meany and Meeking Medical Center . . . **Dr. Quentin F. Knauer** of Cleveland, Ohio, has become associated with **Drs. Jose** and **Alayne Aruguete** at the Sandstone Clinic . . . **Dr. Charles A. Tietz** has joined the Lenont-Peterson Clinic in Virginia . . . **Dr. Daniel Johnson** has joined the Litchfield Clinic . . . **Dr. Thomas G. Birkey** has joined the medical staff of the Montevideo Clinic . . . **Dr. Robert W. Schulz** opened up new offices in Fairmont, and **Dr. Robert Zemke** has joined his father, **Dr. E. E. Zemke**, in the practice of medicine in Fairmont . . . **Dr. Adrian Kapsner** has left the Hutchinson Medical Center to accept a position as resident in radiology with the Veterans hospital in Minneapolis . . . **Dr. George Miks** has joined the staff of the Ely Clinic . . . **Dr. Reginald G. Bickford**, neurophysiologist in the Mayo Clinic, has left Rochester for the Far East and Europe where he will participate in international meetings with other specialists in his field.

* * *

Dr. F. R. Kotchevar has retired from his association with the East Range Clinic at Eveleth and Virginia after thirty-seven years with that group. A testimonial dinner was given by the people of Eveleth in appreciation of **Dr. Kotchevar's** years of service to that community. Future plans of Dr. and **Mrs. Kotchevar** are indefinite at this time.

* * *

At the September 10 meeting of the Southern Minnesota Medical Association the following officers were elected: **Dr. George Stahl**, Austin, President; **Dr. Edmund Burke**, Rochester, First Vice President; **Dr. John J. Eustermann**, Mankato, Second Vice President; and **Dr. Robert H. Conley**, Mankato, Secretary-Treasurer. **Dr. Donald H. Freeman** of the Mankato Clinic received the Bronze Award for the best case report for a paper entitled "Myxedema Coma, Associated with a Suprasellar Tumor," and **Dr. Jack L. Pulec** of Rochester received the Bronze Award for the best paper entitled "Surgical Treatment of Dizziness."

the difference between cough and relief

Benylin® Expectorant

Each fluidounce contains: 80 mg. Benadryl® (diphenhydramine hydrochloride, Parke-Davis); 12 grains ammonium chloride; 5 grains sodium citrate; 2 grains chloroform; 1/10 grain menthol; and 5 per cent alcohol.

for relief of coughs due to colds or allergy

PRECAUTIONS: Persons who have become drowsy on this or other antihistamine-containing drugs, or whose tolerance is not known, should not drive vehicles or engage in other activities requiring keen response while using this preparation. Hypnotics, sedatives, or tranquilizers, if used with BENYLIN EXPECTORANT, should be prescribed with caution because of possible additive effect. Diphenhydramine has an atropine-like action which should be considered when prescribing BENYLIN EXPECTORANT. PACKAGING: Bottles of 4 oz., 16 oz., and 1 gallon.

Brewer Diagnostic Kits

Complete Serological Screening Tests For Syphilis . . .

The RPR Card Tests make use of a specially prepared, carbon-containing RPR Card antigen. The particle size and other characteristics of the carbon is such that when a reactive specimen is encountered, flocculation occurs, and there is a coagglutination which is readily visible to the naked eye. Individual tests, including the collection of blood and separation of plasma can be performed in 7 to 8 minutes.

Confirming earlier findings with the RPR Card Test[1-10] Reed[11] in reporting on 63,800 specimens had an overall agreement of 98.5% in a recent comparative study with other routine screening procedures.

The RPR Card Tests, with their low cost, ease of performance, high sensitivity and specificity, are without peer in situations that demand rapid testing of patients, enabling the physician to initiate prompt treatment of early infectious syphilis.

Specify the RPR Card Test as the screening procedure on serum or plasma samples submitted to your State Approved Laboratory.

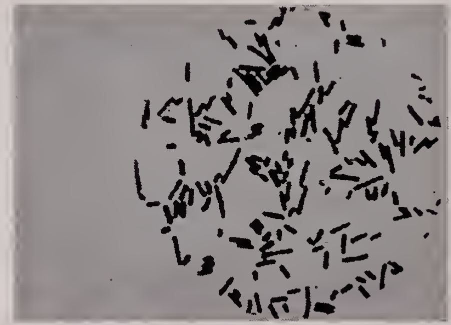
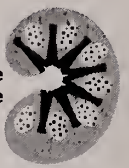
positive thinking about gram-negatives





treat the source
with optimal dosage

NegGram®

Brand of
nalidixic acid

Think of NegGram, the specific anti-gram-negative.

In adults two 500 mg. NegGram Caplets® orally four times a day for one or two weeks will control most gram-negative urinary infections...including many that have proved resistant to other anti-infective agents. NegGram works without causing crystalluria, fungal overgrowth, nephrotoxic or ototoxic effects. Quickly... effectively...with low risk of side effects.

Gram-negative urinary infection —cystitis, pyelitis, pyelonephritis, prostatitis, urethritis? Start first with NegGram.

Indications: Urinary tract infections caused by gram-negative and some gram-positive organisms.

Side effects: Mainly mild, transient gastrointestinal disturbances; in occasional instances, drowsiness, fatigue, pruritus, rash, urticaria, mild eosinophilia, reversible subjective visual disturbances (overbrightness of lights, change in visual color perception, difficulty in focusing, decrease in visual acuity and double vision), and reversible photosensitivity reactions. Marked overdosage, coupled with certain predisposing factors, has produced brief convulsions in a few patients.

Precautions: As with all new drugs, blood and liver function tests are advisable during prolonged treatment. **Pending further experience, like most chemotherapeutic agents, this drug should not be given in the first trimester of pregnancy. It must be used cautiously in patients with liver disease or severe impairment of kidney function.** Because photosensitivity reactions have occurred in a small number of cases, patients should be cautioned to avoid unnecessary exposure to direct sunlight while receiving NegGram, and if a reaction occurs, therapy should be discontinued. The dosage recommended for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Bacterial resistance may develop.

When testing the urine for glucose in patients receiving NegGram, Clinistix® Reagent Strips or Tes-Tape® should be used since other reagents give a false-positive reaction.

Dosage: Adults: Four Gm. daily by mouth (2 Caplets® of 500 mg. four times daily) for one to two weeks. Thereafter, if prolonged treatment is indicated, the dosage may be reduced to two Gm. daily. Children may be given approximately *25 mg. per pound* of body weight per day, administered in divided doses. The dosage recommended above for adults and children should not arbitrarily be doubled unless under the careful supervision of a physician. Until further experience is gained, infants under 1 month should not be treated with the drug.

How supplied: Buff-colored, scored Caplets® of **500 mg. for adults,** conveniently available in bottles of 56 (sufficient for one full week of therapy) and in bottles of 1,000.

250 mg. for children, available in bottles of 56 and 1,000.

GENERAL INFORMATION

Authors

Send manuscripts for consideration to MINNESOTA MEDICINE, 496 Lowry Medical Arts Building, St. Paul, Minnesota 55102.

Bibliographic references should conform to the method used by Index Medicus. A maximum of 12 references will be published, but all references will appear in the reprints.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged. If the drawings are not acceptable they will be commercially reproduced and the author will be billed.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE. The content of the manuscript will not be altered.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Anatomy of
Low Back Pain #1
the sedentary life
is often the seat of
low back pain

The human spine is not engineered fo prolonged sitting at desks, pianos, typewriters and drafting boards. The stresses set up by the heavy, forward-tilted head and trunk, balanced precariously on an insufficient base, result in strain of the dorsal musculature, particularly at the low lumbar level.

The unusual muscle-relaxant and analgesic properties of 'Soma' make it especially useful in the treatment of low back sprains and strains. 'Soma' is widely prescribed ☐ **to relieve pain** ☐ **to relax muscles** ☐ **to restore mobility.**

Indications: 'Soma' is useful for management o muscle spasm, pain, and stiffness in a variety o inflammatory, traumatic, and degenerative musculoskeletal conditions. It also may act to normalize motor activity in certain neurologic disturbances.

Contraindications: Allergic or idiosyncratic reactions to carisoprodol.

Precautions: 'Soma', like other central nervous system depressants, should be used with caution in patients with known propensity for taking excessive quantities of drugs and in patients with known sensitivity to compounds of similar chemical structure, e.g., meprobamate.

Side Effects: The only side effect reported with any frequency is sleepiness, usually on higher than recommended doses. An occasional patient may not tolerate carisoprodol because of an individual reaction, such as a sensation of weakness. Other rarely observed reactions have included dizziness, ataxia, tremor, agitation, irritability, headache, increase in eosinophil count, flushing of face, and gastrointestinal symptoms.

One instance each of pancytopenia and leukopenia, occurring when carisoprodol was administered with other drugs, has been reported, as has an instance of fixed drug eruption with carisoprodol and subsequent cross reaction to meprobamate. Rare allergic reactions, usually mild, have included one case each of anaphylactoid reaction with mild shock and angioneurotic edema with respiratory difficulty, both reversed with appropriate therapy. In cases of allergic or hypersensitivity reactions, carisoprodol should be discontinued and appropriate therapy initiated. Suicidal attempts may produce coma and/or mild shock and respiratory depression.

Dosage: Usual adult dose is one 350 mg. tablet three times daily and at bedtime.

Supplied: Two Strengths: 350 mg. white tablets and 250 mg. orange, two-piece capsules.

Before prescribing, consult package circular.

**for the relief
of low back
sprains and strains**

**SOMA®
(CARISOPRODOL)**

President's Letter

This has been an eventful year for the Minnesota State Medical Association. In the future, 1965 will probably be recorded as a turning point primarily because it marked the advent of government responsibility for the medical care of a large segment of the population. It is too early to determine whether the medical profession will be able to influence the application of this new system of care so that our traditional freedoms will be reasonably maintained or whether truly socialized medicine will make its first great inroad. There are forces within our society which can be mobilized behind the ideals of medical freedom effectively enough to preserve them. Intelligent political action by the medical profession and its allies will be necessary to accomplish this since it seems evident that political action has been effective in molding the changes now upon us.

If medicine is to function with freedom under a system primarily voluntary or with comparable freedom under government sponsorship, it seems to me that the profession must be organized to demonstrate to the public that the best possible care is readily available to all. Standards of excellence must be determined and the methods of ensuring them must be strengthened. In this endeavor no factor is more important than a friendly and effective cooperation between hospitals and their medical staffs. Medicine needs spokesmen who can interpret adequately our ideals to all segments of society including those which are politically oriented.

With these thoughts I come to the end of my term of office. To all of our membership I give my thanks for the opportunity to have served, and for the cooperation of those who have labored with me in the affairs of the Minnesota State Medical Association I am grateful.

It is a pleasure to acknowledge the efforts of the editor of this journal, Dr. Carl Rice, in producing and maintaining a superior publication. In this special issue we salute the Downstate Medical Center of the State University of New York and its president and dean of the College of Medicine, Dr. Robert A. Moore. This Brooklyn institution has strong ties with Minnesota. Dr. Dennis, the chairman of the Department of Surgery, was associated with the University of Minnesota for 16 years. Several eminent members of the faculty, Dr. Millins in radiology, Drs. Karlson, Enquist, Kaplan, and Fries in surgery, received their training in Minnesota, and Downstate Medical Center has contributed a Markle Scholar, Dr. Eugene Bernstein, to Minnesota. The Downstate Medical Center is the only medical school in Brooklyn and Long Island, an area with 7,000 physicians and a population of 4½ million. Dr. Moore writes that "We hope many of our Minnesota colleagues will be encouraged by this special issue to pay us a visit." We welcome these contributions which were prepared under the supervision of Dr. Dennis.

Low host resistance?

Consider the "extra" antibacterial activity of Ilosone®

Occasionally, therapeutic failure is due to the patient's inability to mobilize his defenses sufficiently to overcome infection. Typical of this is the debilitated patient, the premature infant, or the diabetic. It is in these patients that the high levels of antimicrobial activity of Ilosone are especially useful. Ilosone has demonstrated antibacterial levels two to four times those of erythromycin base or stearate. Furthermore, it attains them earlier and maintains them longer. Even the presence of food does not appear to affect the activity of Ilosone.

Contraindications: Ilosone is contraindicated in patients with a known history of sensitivity to this drug and in those with preexisting liver disease or dysfunction.

Side-Effects: Even though Ilosone is the most active oral form of erythromycin, the incidence of side-effects is low. Infrequent cases of drug idiosyncrasy, manifested by a form of intrahepatic cholestatic jaundice, have been reported. There have been no known fatal or definite residual effects. Gastro-intestinal disturbances not associated with hepatic effects are observed in a small proportion of patients as a result of a local stimulating action of Ilosone on the alimentary tract. Although allergic manifestations are uncommon with the use of erythromycin, there have been occasional reports of urticaria, skin eruptions, and, on rare occasions, anaphylaxis.

Dosage: *Children under 25 pounds*—5 mg. per pound of body weight every six hours. *Children 25 to 50 pounds*—125 mg. every six hours. *Adults and children over 50 pounds*—250 mg. every six hours. For severe infections, these dosages may be doubled.

Available in Pulvules®, suspension, drops, and chewable tablets. Ilosone Chewable tablets should be chewed or crushed and swallowed with water.

Ilosone®

Erythromycin Estolate

THE "DUMPING SYNDROME" which occurs after gastric resection consists of sweating, unpleasant warmth, subjective flushing, nausea, palpitation, and explosive diarrhea, during or within 15 minutes after eating and lasting up to 45 minutes. These symptoms are partially or completely relieved by lying down.

The most widely accepted explanation is a loss of circulating plasma volume into the intestine. This was suggested by Roberts and associates,[1] who used the observation of Lapp and Diebold[2] that the instillation of 50 per cent glucose into the jejunum can reproduce most of the signs and symptoms of the "dumping syndrome." On the other hand, Butz[3] found that during "dumping" induced in this manner the plasma volume was maintained. Amdrup and associates[4] noted that the decrease in plasma volume was less than the volume of fluid accumulating in the small intestine, while the loss from the thiocyanate (interstitial) space was approximately equal to the increase in intestinal intraluminal volume.

A second current theory for the production of the "dumping syndrome" relates the symptoms to the release of serotonin from the argentaffin cells of the duodenum and jejunum.[5-9] The thesis here is that the observed increase in intestinal activity, the explosive diarrhea, the flushing, the sense of warmth and of faintness are secondary to the action of serotonin. Increased serotonin in the portal venous blood has been observed on exposure of the small intestine to hypertonic solutions such as 50 per cent glucose.[6]

A third mechanism was suggested by Machella,[10] namely, that there is distention of the jejunum and duodenum caused by the introduction of hypertonic materials into the small intestine. Machella was able to produce

most of the symptoms of "dumping" by blowing up a balloon in this segment of the intestine.

It appears to the authors that these explanations and the several now discarded theories of the origin of the "dumping syndrome" singly or in conjunction fail to explain the symptoms observed. Because hypertonicity appears to be the common denominator in all of the prevailing theories of the cause of the "dumping syndrome," we have studied the effect of intraluminal placement of hypertonic solutions on intestinal absorption and motility in the conscious dog.

Procedure

To study absorption under circumstances in which the small bowel does osmotic work, a 40-cm. ileac Thiry-Vella loop[11] was prepared, in which both ends of the segment isolated from the main intestinal stream were brought out through the left flank. Twenty-five ml. of a solution half-isotonic in NaCl and half-isotonic in Na_2SO_4 was introduced over a 60-second period into the loop at body temperature, and the ends were closed with conical stoppers. Samples of 0.2 ml. were drawn every 10 minutes over the next hour, and the chloride concentration in the specimens was measured with a Buchler Cotlove Chloridometer. Following the control determinations, the loop was bathed with 25 ml. of 50 per cent glucose (37° C) in water for five minutes. The segment was then gently flushed out with chloride-sulfate test solution, and 25 ml. of test solution was instilled into the lumen as in the control observation. Specimens of 0.2 ml. volume were removed every 10 minutes for one hour and analyzed for chloride content.

Motility patterns of the main stream of the small bowel were recorded through open-tipped water-filled polyvinyl catheters of 1.4 mm. internal diameter. The catheters were introduced into a jejuno-cutaneous Roux-Y preparation,[12] and intraluminal pressure changes were detected with a strain gauge and recorded on a Sanborn multichannel recorder.

All animals were studied in the fasting state without the use of anesthetics or narcotics and with the animal lying on his right side.

Results

The Effect of a Hypertonic Solution on the Absorption of Chloride from an Ileac Thiry-Vella Loop

When 25 ml. of a solution which is half isotonic in NaCl and half isotonic in Na_2SO_4 is placed within the Thiry-Vella loop, more than 90 per cent of the fluid is absorbed from the loop within 60 minutes, and the chloride concentration falls from 71 mEq/L to 10 mEq/L (Figure 1). Data from 12 experiments show a 50 per cent average drop in chloride concentration in 20 minutes.

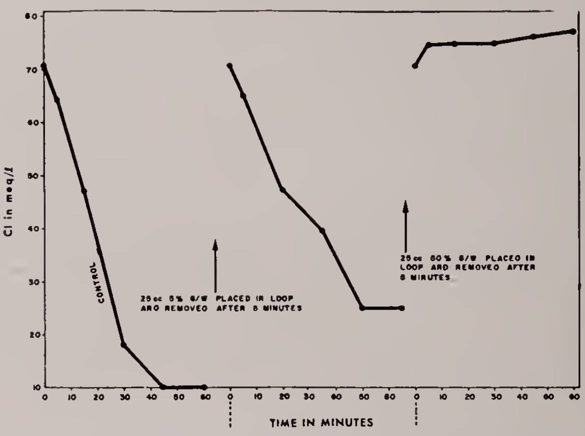

Fig. 1 — When 25 ml. of a test solution half-isotonic in NaCl and half-isotonic in Na_2SO_4, which contains 78 mEq/L of chloride ion, is placed in a Thiry-Vella loop, the chloride concentration in the loop drops to 10 mEq/L over the 60-minute test period. This is the control state. After the loop is washed with 5 per cent glucose in water for five minutes, a similar pattern of chloride absorption is obtained. However, when the loop is washed for five minutes with 50 per cent glucose in water, there is no chloride absorbed over the test period of one hour.

When the loop is washed with 25 ml. of 5 per cent glucose in water (37° C) for five minutes and the NaCl-Na_2SO_4 solution then instilled, a similar pattern of chloride absorption is obtained.

On the other hand, when the loop is washed with 25 ml. of 50 per cent glucose in water (37° C) for five minutes, there is no appreciable absorption of fluid or chloride ion from the subsequently instilled NaCl-Na_2SO_4 solution over the test period of one hour.

In three experiments, control observations of chloride absorption from the test solution were followed by multiple observations of chloride absorption after a single five-minute period of flushing with 50 per cent glucose solution. All remaining fluid was flushed out of the segment with test solution every 20 minutes over a two and a half hour period, and chloride concentration was followed through each 20-minute interval. There was return of some selective absorption of chloride ion only after one and a half hours following the 50 per cent glucose wash. At 100 minutes after the 50 per cent glucose instillation, the ileum reduced the intraluminal chloride concentration from 80 mEq/L to 66 mEq/L in 20 minutes, as compared to the control of 80 mEq/L to 38 mEq/L in 20 minutes. Return to control performance did not occur in two and a half hours (Figure 2).

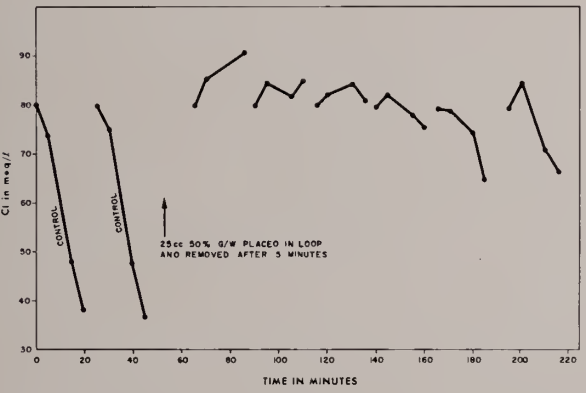

Fig. 2 — When 25 ml. of a test solution half-isotonic in NaCl and half-isotonic in Na_2SO_4, which contains 78 mEq/L of chloride ion, is placed in a Thiry-Vella loop, the chloride concentration in the loop drops to less than 40 mEq/L in 20 minutes. After the loop has been washed with 50 per cent glucose in water for five minutes, chloride absorption from the test solution is impaired. New test solution was placed in the loop every 20 minutes, and only after 120 minutes following the 50 per cent glucose in water does the absorption of chloride ion from the test solution begin to return to control rates.

Chloride absorption was also studied repeatedly in a dog which had both a Thiry-Vella loop and a jejuno-cutaneous Roux-Y anastomosis. When 50 per cent glucose in water was instilled into the bowel through the Roux-Y anastomosis, and chloride absorption from the instilled NaCl-Na_2SO_4 solution was measured simultaneously in the Thiry-Vella loop, a normal pattern of chloride absorption was obtained.

The Effect of Hypertonic Solutions on Jejunal Motility

A triple-lumen catheter with openings 5 cm. apart was introduced into a jejuno-cutaneous Roux-Y preparation, and a record of jejunal pressure patterns as shown in Figure 3 was obtained. After a period of control observation, 50 ml. of 50 per cent glucose in water at 37° C was instilled at a rate of 10 ml./minute into the bowel at a point 5 cm. distal to the recording catheters. Within five minutes of the instillation of the hypertonic solution there was a cessation of activity without a bout of initial hyperactivity. In each of 13 trials, this cessation of activity began from zero to eight minutes after the beginning of injection of 50 per cent glucose in water and persisted for periods of 35 to 215 minutes, at which time the motility gradually returned to control levels. This period of induced inactivity of the bowel was usually associated with the animal becoming drowsy. In only two of nine trials was any cessation of intestinal motility produced following the instillation of 50 ml. of 0.9-per cent NaCl into the Roux-Y fistula. Motility was abolished for 60 minutes in one and for 89 in the other.

Discussion

This study demonstrates that 50 per cent glucose abolishes the ability of the ileac mucosa to absorb chloride against an osmotic gradient as well as to absorb water. This performance of osmotic work is inhibited for periods of up to two and a half hours following the exposure of the ileac mucosa to 50 per cent glucose. Following this period, the absorption rate of chloride returns towards normal.

This action of 50 per cent glucose appears to be local. The absorption of chloride from the ileac Thiry-Vella loop was not impaired when 50 per cent glucose was instilled simultaneously into the jejunal Roux-Y fistula.

The course of the chloride concentration in the ileum in the presence of sulfate ion has been well documented in a series of excellent studies by Ingraham and Visscher.[13]

Confirmation in the Chronic Thiry-Vella loop preparation in the dog was obtained by Dennis and Visscher.[14] The possibility that gastric content or 50 per cent glucose solution might interfere with performance of osmotic work by the intestinal mucosa was suggested by the prior demonstration by one of us[15] that pure water has such an effect upon the jejunal and ileac mucosae. It is this observation that suggests that the effects of 50 per cent glucose here reported may be osmotic in mechanism rather than due to the chemical nature of glucose. Hendrix et al.[16] have demonstrated that intravenous infusion of serotonin is followed by a brief period of hyperactivity of the bowel before cessation of all activity and decrease in tone.

Summary

The effect of 50 per cent glucose on chloride absorption against an osmotic gradient has been measured in the trained, conscious dog, using a chronic Thiry-Vella loop of ileum. Fifty-per cent glucose in water inhibited the ability of the ileac mucosa to perform osmotic work as measured by absorption of chloride against a concentration gradient; 50 per cent glucose was also found to inhibit jejunal motility following instillation into a chronic Roux-Y jejuno-cutaneous preparation in the unanesthetized dog.

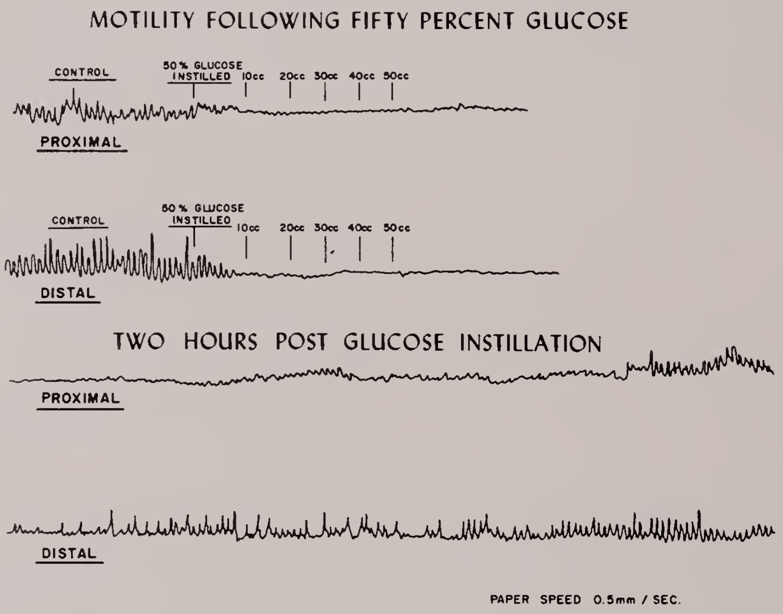

Fig. 3 — The control recording of jejunal pressure patterns consists of regular rhythmic contractions. The recording catheters are in the jejunum with the ends 5 cm. apart. Following the instillation of 50 ml. of 50 per cent glucose in water into the bowel at a rate of 10 ml./min., there is an almost immediate cessation of activity. Only after two hours does the motility return to control levels.

Pigskin Heterografts*

B. E. BROMBERG, M.D.**
I. C. SONG, M.D.†
Brooklyn, New York

ALTHOUGH THE need is admittedly small, whenever the demand for a temporary biological dressing arises, despite the urgency it is often difficult to obtain an adequate supply of suitable tissues, whether from living donors, cadavers, or tissue banks. This need for human-skin substitutes for burn victims prompted many early investigators to search for materials from animal sources. All of the efforts were doomed to failure, however, since the goal envisioned was either complete repair or permanent survival of the heterografts.

Recently, however, several investigators have suggested that heterologous tissues be used as temporary dressings for large skin defects. In 1951, Silvetti[1] proposed that a major study be undertaken to determine the practicality of using bovine embryo skin as a temporary form of biological dressing for large skin wounds, based on preliminary results from mice, rats and rabbits. In 1955, Silvetti and Menendez[1] described the use of calf-embryo skin in a 72-year-old housewife, with the graft being retained for more than two weeks. More recently, Silvetti and co-workers[1] reported that grafts of such skin persisted for eight to 16 days in mice, rats, rabbits and dogs, and left clean, smoothly granulating wounds after being sloughed. Second set grafts were retained for nine to 10 days. In addition, microscopic examination of the grafted areas showed less round cell infiltration about the bovine graft than in control homografts. Rogers and co-workers[2,3] have utilized fetal calf in humans and observed a surprising lack of host reaction to the grafts, even after 12 to 17 days of graft retention. Sokolic[4] and co-workers, however, evaluated the use of bovine embryo grafts in dogs and humans and reported that the grafts elicited a violent polymorphonuclear reaction at the graft host interface and were not effective more than four to five days.

Snyderman and co-workers[5] studied the survival of homografts and pigskin heterografts in patients with neoplastic disease and observed that pigskin was retained for more than seven days in nine out of ten patients, with two cases of prolonged survival. One patient died with the heterograft‡ still intact after 33 days; the second patient retained the heterograft for 68 days. At the same time, no antibodies against pigskin could be demonstrated in the serum of six of these patients. Eastwood[6] has also investigated the use of pigskin and found that freeze-dried pigskin remained firmly adherent and provided effective coverage for wounds in rats for an average of 14 days as compared with 21 days for freeze-dried homografts. Fresh pigskin which had been sterilized with betapropiolactone was effective for approximately 10 days. Two clinical cases were reported in this study.

Other materials which have been suggested as suitable for temporary dressings are amniotic membrane, reconstituted collagen, and open-celled polyvinyl-alcohol-formalized and polyurethrane foams. Amniotic membrane, however, does not provide the effective coverage of other materials; generally speaking, rejection times are shorter than in skin, and the thickness of the material (.2 mm–.5 mm.) prevents its use in weight-bearing areas. The narrow connective tissue zone at the graft donor interface, as would be anticipated, shows a robust inflammatory response by the seventh day. Bovine collagen is effective experimentally for approximately 14 days; however, the application of either the film or the sponge has been entirely unsatisfactory clinically as a temporary dressing in burns, and maceration and disintegration seem to be inevitable consequences. The sponges do not sufficiently adhere to the wound surfaces, and fluid collections are frequent at the wound interface. Furthermore, rigidity develops on drying, preventing its use at crease areas, and fragmentation of the protheses has occurred, with migration into the tissues.

Method of Study

The urgent need for physiological skin-wound dressing material which could not be met by homografts alone, and the encouraging results of previous investigators stimulated the search for additional skin substitutes. Abundantly available, heterogenous skin was employed in the animal laboratory, using White Yorkshire pigskin and bovine collagen as graft sources. White Yorkshire pigs were selected as donors because:

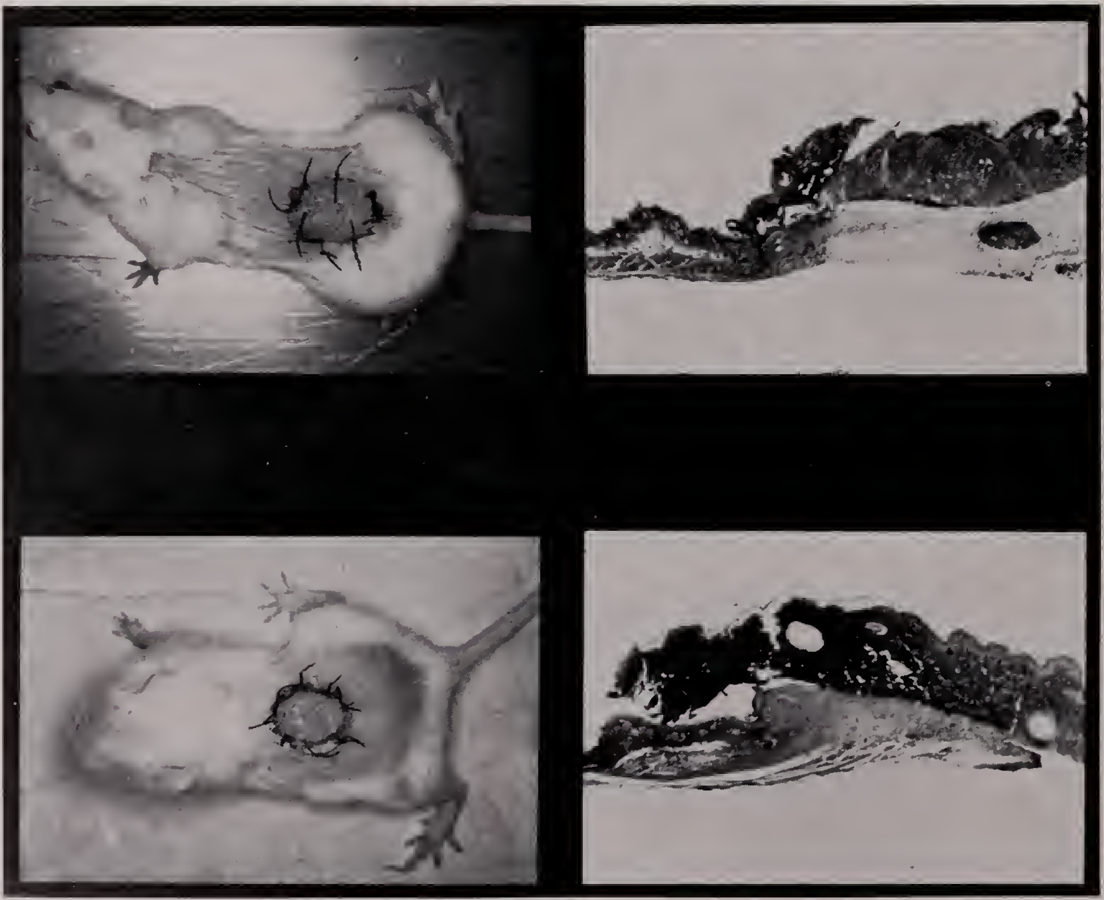

Fig. 1 — *Upper Left:* Pig heterograft on mouse at six days. Graft is soft, pink and viable. *Upper right:* Masson-stained section of six-day heterograft showing good structural integrity and little cellular infiltration. *Below left:* Pig heterograft in situ for 14 days. Essentially the same as six days except for a slightly increased dehydrated necrotic peripheral rim. *Lower right:* 14-day biopsy showing a progression of the necrotic edge; however, the structures are intact and there is little cellular infiltration.

1. Pigskin has close structural similarity to human skin.
2. There is a sparsity of hair as compared to the skin of other animals.
3. There is a readily available unlimited supply.
4. There is technical ease in obtaining split-thickness skin from the wide and tense body surface.
5. Repeated crops of skin in a short period of time are available due to the rapid re-epithelialization of skin.

Over 800 laboratory animals have been employed in varying studies to date, and 24 patients have received one or more applications of pigskin.

Results

In all of the studies, and in the patients selected, the lack of host reaction to the pigskin has been most impressive.

Table 1 is a resume of the results in homografting and in pigskin heterografting in C57 and A Heston mice (Fig. 1). It is interesting to note the retention of the pigskin heterografts for an average of 18 days as against an average of nine days for the homografts. In all of these studies the primary interest was to gain information as to the eventual use of pigskin as a temporary biological dressing, not to seek prolonged survival of pig heterografts. Irradiation of the pigskin in vitro did not materially alter our results, and second set pigskin grafts did not show accelerated responses. Vascularity studies employing Evans blue, India ink and polyvinal-pyrollidone labelled with I^{131} failed to reveal any evidence of vasculariza-

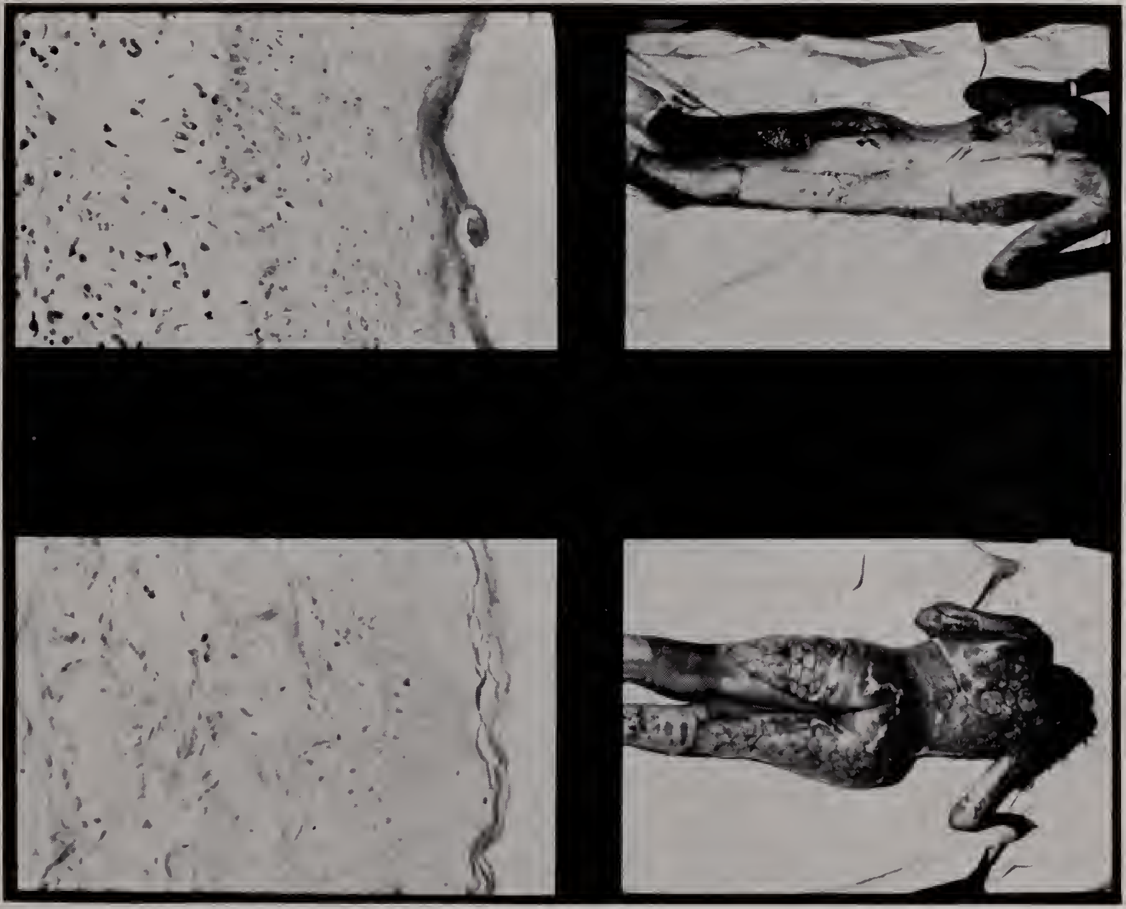

Fig. 2 — *Upper left:* Pigskin grafts five days after application to a 51% third degree burn. The grafts have good adherence, appear viable and provide effective coverage. *Lower left:* Section of the pigskin graft at eight days showing intact dermis and epidermis with little or no cellularity. *Lower right:* Normal skin with the human dermis staining a lighter green in the Masson preparation. Upper right: Patient seven months after burning and subsequent auto grafting.

tion of the pig heterografts in any of the animals examined. Freeze-dried pig grafts were also successfully retained when employed for temporary coverage. Massive grafts applied to huge wounds were remarkably satisfactory and life-saving in mice as compared to ungrafted controls, all of which succumbed within 40 hours.

Table 2 is a compilation of the results when split-skin pig grafts were applied to New Zealand white rabbits. Again longer retention was obtained with these heterografts as compared to split-skin rabbit homografts. Longer retention was also obtained in the pig grafts when animals were simultaneously homo and heterografted.

Table 3 summarizes our experience with pigskin as a temporary skin substitute in 19 patients, 14 of whom were seriously burned, although at this time an additional five patients have been heterografted (Fig. 2). None of the grafts were sutured and repeated applications were made in nine patients. In most instances the grafts have been retained for an average of two weeks. As in the use of any type of temporary covering agent, the degree of adherence and length of retention are to a large degree dependent upon the status of the wound surface upon which the grafts are applied. Whenever purulent accumulations were observed under the heterografts, the involved grafts were removed. No detrimental effects have been observed in these cases to date, although the data accumulated so far is incomplete, particularly in the immunological and bacteriological aspects.

MEAN SURVIVAL OF SKIN GRAFTS

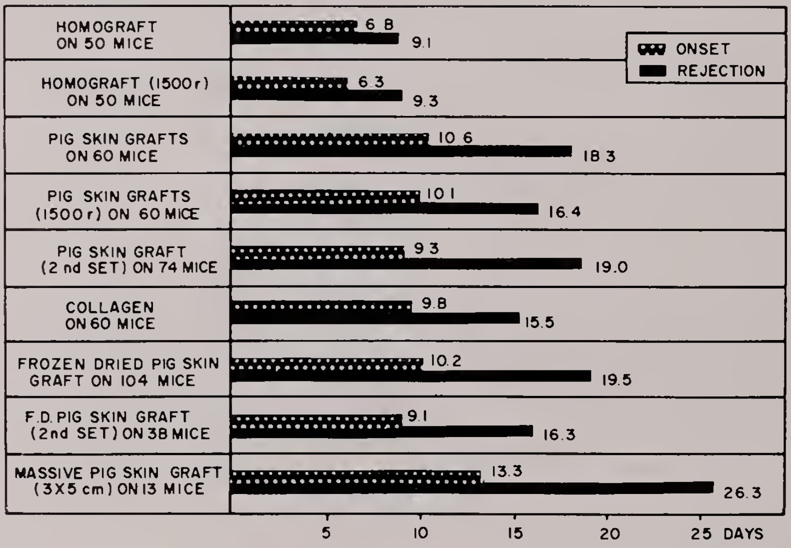

TABLE 1

MEAN SURVIVAL OF SKIN GRAFTS

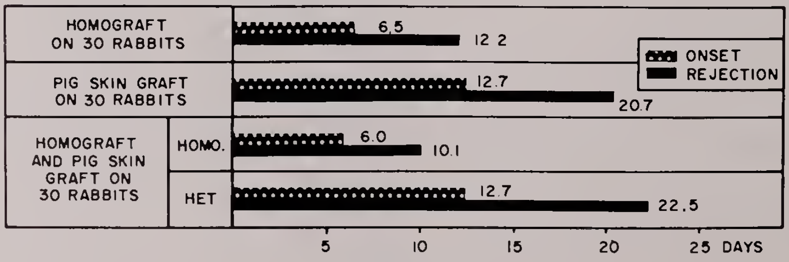

TABLE 2

Summary

An ideal temporary dressing should develop firm adherence to the wound surface, thus preventing protein and electrolyte loss, decreasing pain, and inhibiting the fibroplastic response. In addition, it should reduce bacterial growth, permit less painful dressing changes, and improve the patient's general well being. The application of biological materials over joint surfaces may even permit painless motion and conceivably reduce the degree of contractures. There can be no doubt that the judicious use of homografts in severe burns, regardless of the source, method of preservation, or state of viability, and also despite some obvious disadvantages, has proven its clinical usefulness. On the other hand, pigskin heterografts appear to offer several advantages. They remain viable in the neighborhood of two weeks and provide effective wound coverage. Repeated applications can be made without any noticeably adverse local or systemic responses, and without the slough accompanying the homograft rejection mechanism. In most instances, the application of heterografts, as in other temporary biological dressings, exerts a beneficial influence upon the wound surface, both from the standpoint of a reduced bacteriological population and a stimulating effect upon the marginal epithelium. Although pigskin has provided as effective wound coverage as other more commonly employed temporary biological dressings, it would appear at this time that it should be reserved for urgent situations where homografts are not available.

Easy Street

Easy street is always a dead-end street or a blind alley — Herbert Prochnow

Cerebral Gigantism

In 1964, Sotos, Dodge, Muirhead, Crawford and Talbot[1] reported five cases of gigantism characterized by mental retardation, clumsiness, hypertelorism, anti-Mongolian slant of the eyes and a high arched palate.

These authors discussed their cases in the light of a possible hypothalamic lesion, relating the growth disturbance to some impairment of growth-hormone release or nutritional processes.

For the past four years, the author has followed a patient of remarkable similarity except for two features: a persistent elevation of the urinary excretion of 17-ketosteroids and hydroxysteroids and an anatomical urinary tract abnormality.

The case is of interest because although it appears almost identical to the previously described group, there is demonstrable abnormal adrenal function. Here it is again attractive to postulate a hypothalamic lesion, but in this case it would appear that major emphasis should be given to those factors that control adrenocorticotropin release. The gigantism seen here may be more related to adrenal androgens than to excessive growth-hormone release and/or nutrition.

Case Report

A 3½-year-old white boy (Figure 1) was first admitted to Kings County Hospital on February 25, 1961, because of a febrile convulsion. There had been a previous episode at age 8 months. He was the product of a full-term pregnancy (complicated by pre-eclampsia), with a birth weight of 11 pounds, 9 ounces. Delivery was by cesarean section because of "increased intracranial pressure." Developmental history revealed that the patient sat at 8 months of age, stood at 13 months and talked at 2½ years. At the time of admission, he was not yet toilet-trained and was considered by his parents to be somewhat retarded when compared to his siblings. The patient's mother was not diabetic, although her mother was.

The father's height is 5 feet, 11 inches, the mother's 5 feet, 4 inches, a 19-year-old brother's 6 feet, a 14-year-old brother's 5 feet, 10 inches, and a 12-year-old sister's 5 feet, 4 inches. The tallest relative is the maternal grandfather whose height is 6 feet, 4 inches.

Physical Findings

The physical examination revealed a large, awkward child, 48 inches tall (50th percentile for 7 years), weighing 57 pounds (50th percentile for 7 years). His head circumference was 21.5 inches (50th percentile for 13 years). The ratio of the upper to lower segment was 1.3 (normal for age). His head was remarkable in that the shape was dolichocephalic (Figure 2), with hypertelorism and an anti-Mongolian slant to the eyes (Figure 3). The palate was high arched and the teeth carious. Hyperemia of the pharynx was present. There was no palpable splanchnomegaly. At this time, the genitalia were considered to be of normal size for the patient's age.

Abnormal Urinary Corticoid Excretion

MURIEL KOWLESSAR, M.D.*
Brooklyn, New York

Laboratory Findings

A spinal fluid examination revealed no abnormalities. Admission blood count and urine analysis were normal except for leucocytosis and acetonuria. The BUN was 9 mg%. Serum CO_2 was 13.4 mEq/L, Cl 103 mEq/L, Na 135 mEq/L, K 4.7 mEq/L. The following results were obtained with an oral glucose tolerance test: (1) fasting level — 91 mg%, (2) 30 minutes — 119 mg%, (3) 1 hour — 119 mg%, (4) 2 hours — 119 mg%, (5) 3 hours 109 mg%. An insulin sensitivity test gave the following results: (1) fasting glucose level — 119 mg%, (2) 15 minutes — 86 mg%, (3) 30 minutes — 70 mg%, (4) 45 minutes — 90 mg%, (5) 60 minutes — 61 mg%, (6) 90 minutes — 50 mg%. The 24-hour urinary excretion of 17-ketosteroids was 4.0 mg. and of 17-hydroxycorticosteroids 6.5 mg. There were no detectable gonadotropins in the urine. Skeletal maturation was estimated as falling within 2 standard deviations of the mean, although approaching the 95th percentile. On the skull film the measured area of the sella turcica fell within 2 standard deviations of the mean, also approaching the 95th percentile. The electroencephalogram showed a diffuse abnormality compatible with a convulsive disorder.

In June 1961, pneumoencephalography was performed. The x-ray report was as follows: "Enlarged calvarium with a proportionate ventricular system. No inordinate amount of gas is seen within the subarachnoid space, so that the above described findings are indicative of a macrocephaly."

Progress

There were two subsequent admissions for evaluation of clumsiness and for recurrent convulsions.

At age 4 and 7/12 years, a repeat bone age was equivalent to that of an 8-year-old male, this being greater than 3 standard deviations above the mean. At this same time urinary 17-ketosteroid excretion was 12.3 mg. per 24 hours.

At about the age of 6 and 11/12 years a diagnosis of urinary tract infection was made by the patient's private physician. The child was then readmitted to the hospital for evaluation of this

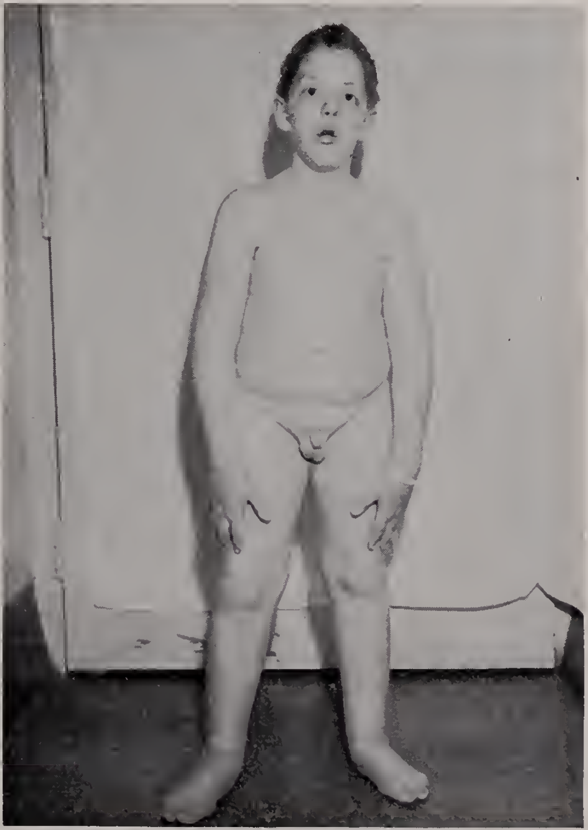

Fig. 1 — Seven and 4/12 year-old male.

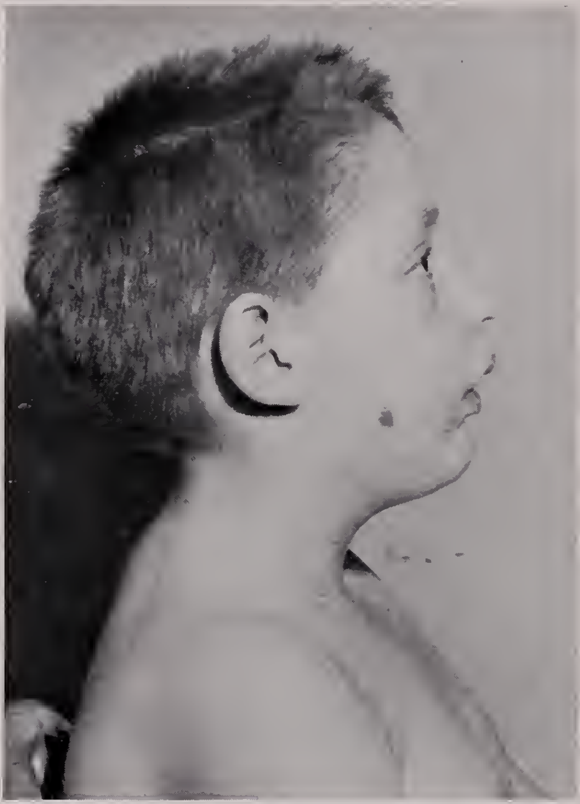

Fig. 2 — Head is dolichocephalic.

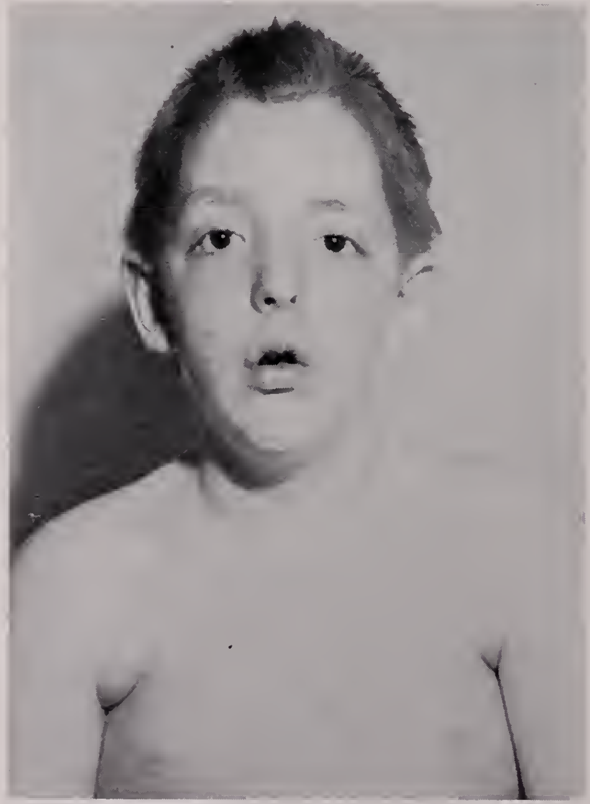

Fig. 3 — Eyes are widely spaced and show an anti-Mongolian slant.

problem. At this time the physical examination was unchanged, except that his height was 53 inches (mean for 10-year-old male), his weight 125 lbs. (50th percentile for 15½-year-old male), and his head circumference 23 inches (greater than 50th percentile for 13-year-old male). His genitalia appeared somewhat large for a prepubescent male. There was no pubic or axillary hair present.

Admission urine analysis was negative except for the presence of many white blood cells. BUN was 11 mg%. A cystogram showed the presence of "megacystis" and "megaureter" of unknown etiology, associated with an impaired ability to empty his bladder. (Bladder training was said to have been achieved by 5 years of age.) Creatinine clearance at this time was about 45% of the expected normal.

Twenty-four-hour urinary corticoid excretion remained high. The unstimulated values for 17-ketosteroids and 17-hydroxycorticosteroids were both 10 mg. Repeat serum electrolytes, glucose tolerance and insulin sensitivity curves were not significantly different from the studies performed 4 years earlier.

Baseline plasma 17-hydroxycorticosteroids were elevated on 2 occasions (32 and 29 ug% — upper limit of normal adults, 25 ug%). There was a normal response to intravenous ACTH stimulation (plasma hydroxycorticosteroids rose from 32 to 71 ug%). On the other hand there was no response to oral metapirone. The PBI was 4.4 ug%. Bone age was equivalent to that of a 10½-year-old child, representing 3 standard deviations above the mean. Both repeat films of the skull and another pneumoencephalogram were unchanged from the previous studies.

His I.Q. on the Stanford-Binet scale was 79.

Discussion

When the case was first seen, an attempt was made to determine the cause of the gigantism. Conditions recognized as being associated with accelerated growth, such as thyrotoxicosis, Marfan's syndrome, gigantism associated with lipodystrophy as described by Seip[2] could be ruled out on the basis of inspection. Adrenal disorder was not considered at this time, because the 17-hydroxysteroids did not seem remarkably elevated when interpreted in the light of the patient's large size, and the elevated 17-ketosteroids were not thought to be high enough to suggest the adrenogenital syndrome (especially in the absence of genital enlargement at that time). The investigation was, therefore, directed at ruling out pituitary gigantism associated with excessive growth-hormone secretion.

The presence of a markedly advanced bone age made this diagnosis unlikely.[3] The presence, also, of a large abnormal head and mental retardation made one consider that these features might be part of a symptom complex.

Additional factors which seemed to rule out gigantism associated with excessive growth hormone production included: (1) no demonstrable enlargement of the sella turcica, (2) excessive size at birth, (3) absent visceromegaly, (4) normal serum P, (5) a flat glucose tolerance test, (6) increased sensitivity to insulin. Not only do the two latter findings argue against excessive growth-hormone secretion, but they suggest that its secretion may be impaired. There is experimental data to support this theory. In 1948, Kinsell et al.[4] demonstrated that the treatment of acromegalics with androgens would cause a fall in serum growth-hormone levels. More recently, Frantz and Rabkin[5] have shown that treatment of patients with corticosteroids impairs the ability to secrete growth hormone.

The discharge diagnosis after the first admission was "gigantism of undetermined etiology."

The similarity between Sotos' cases and the present one is striking. The author's case shares with all or most of the five previously reported the following features: (1) mental retardation, (2) clumsiness, (3) hypertelorism,* (4) anti-Mongolian slant of the eyes, (5) high arched palate, (6) convulsive disorder, (7) abnormally large dolichocephalic head, (8) precocious sexual maturation, (9) normal sella turcica, (10) advanced bone age, (11) abnormal pneumoencephalogram, (12) maximal growth spurt ending at about four years of age (Figure 4), (13) undetectable urinary gonadotropins, (14) abnormally heavy birth weight, (15) negative family history for gigantism, (16) no laboratory findings compatible with excessive secretion of growth hormone.

The present case is unique in two features: (1) the presence of an associated urinary tract abnormality, and (2) marked elevation of the excretion of both 17-ketosteroids and 17-hydroxycorticosteroids. The first feature is considered to be a coincidental finding, unrelated to the growth problem; but the second is thought to be a variant of cerebral gigantism.

Sotos and his co-workers postulated that a hypothalamic lesion could lead to an alteration in the regulation of nutrition and/or growth-hormone release, thereby offering an explanation for the gigantism seen in their case. It should be added that Sotos et al. did not report 17-hydroxycorticosteroid values in any of their cases, nor 17-ketosteroids in two. Therefore, it cannot be stated that all of their cases lacked any disturbance in adrenal function.

The present author would also like to suggest a hypothalamic lesion in this case, but to postulate that excessive growth is related to an abnormality of the hypothalamic (hypophyseal) adrenal axis rather than to excessive growth-hormone release.

Reichlin[6] has shown that in rats the site of hypothalamic lesions which cause disturbance in growth is close to, if not identical with, the site which causes disturbances in adrenocorticotrophic hormone release.

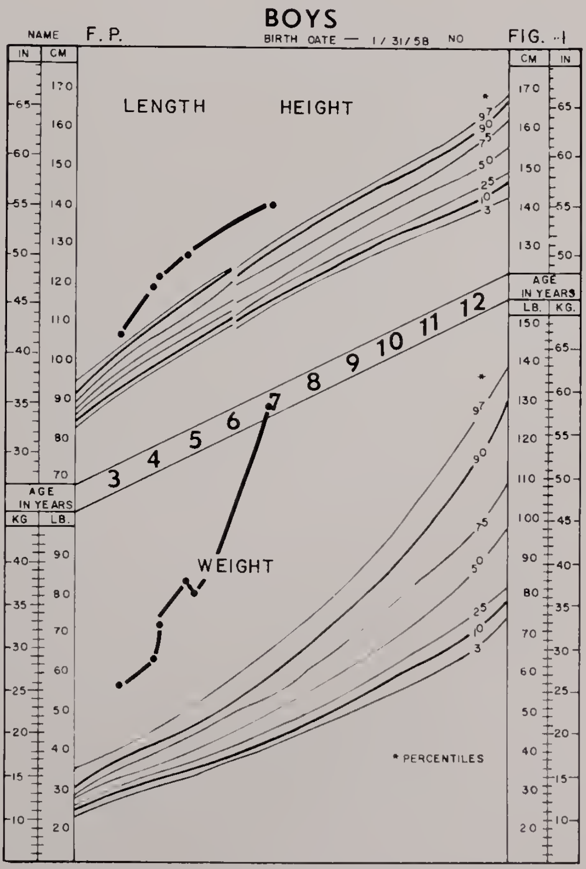

Fig. 4 — Maximum linear growth spurt is seen between ages 3½ and 4½ years.

Summary

A case of excessive growth in childhood has been presented. This patient demonstrates anatomic and developmental features which appear identical with a previously described group. The present case differs from the earlier ones in that there are quantitative abnormalities of adrenal hormone production, which are considered secondary to the manifest central nervous system disorder. Anatomical considerations support the citation of this case as a variant of the disease previously reported as cerebral gigantism.

IT'S THE LAW

Deductibility of Travel Expenses as Educational Expenses

Travel expenses necessarily incurred are deductible as educational expenses if the taxpayer can show that his itinerary was chosen and the major portion of his activities during the trip was undertaken for the primary purpose of maintaining or improving skills required in his business or profession. However, problems arise when, in the course of vacation travel, side-trips are taken to places where the taxpayer may receive knowledge which may be of educational value to him in his business or profession. For example, an American surgeon might be benefited in his profession by observing the performance of a delicate operation by a renowned European surgeon, or an American lawyer might profit by watching English barristers conducting a trial. These isolated deviations from their vacation travels would not entitle them to deduct all of their travel expenses. The extent to which travel expenses would be deductible, as educational expenses, would depend on the facts of the particular case.

Astrology and Medicine

The sun is a fiery and cardinal astrological sign. Disturbances in its vital, expansive force result in corresponding disturbances in those physiological functions that are solar-controlled, principally those involving the heart, the spine, and the spleen. The moon is a watery, mutable sign. When afflicted it disposes to complaints resulting from disorders of the body fluids and mucous membranes, and also to female disorders and pathologies of periodic manifestation.

The sun's energy is electric, the moon's magnetic.

Drawing on my fine command of language, I said nothing. — Robert Benchley

Dialysis Therapy on a Medical Service*

ELI A. FRIEDMAN, M.D.**
Brooklyn, New York

In 1877 Wegner demonstrated that irrigation of the peritoneum of rabbits with concentrated sugar solution would permit the collection of a larger volume of fluid than had been initially instilled.[1] During the next 40 years several investigators showed that the intraperitoneal injection of hypotonic solutions in rabbits and dogs was followed by a rapid depletion of the volume of instilled fluid. It was also shown that solute could pass across the peritoneal membrane, the direction of net flux being determined by the concentration gradient. Numerous attempts to substitute for failing renal function by employing the semipermeable membranes of the body to effect transfer of accumulated body urea into rinsing fluids were reported from 1920 through 1940. The stomach, small intestine, pleural cavity, lung, bladder, and vagina were tested for their suitability as dialyzing surfaces, but the most promising body cavity appeared to be the abdomen because of the large surface area, approximately two square meters in man, of the serosal peritoneum.

Grollman, Turner and McLean in 1951 reported that bilaterally nephrectomized dogs which usually live a maximum of three to five days could be kept alive up to 70 days by repeated peritoneal dialysis.[2] This experimental observation found clinical application in the 1953 study of LeGrain and Merrill which noted that short-term continuous peritoneal irrigation was an effective method of removing solute and water from the oliguric patient with concomitant prolongation of life.[3] The development of disposable plastic cannulas and the commercial availability of

peritoneal dialysis solutions in 1958 stimulated further interest in the possible applications of this method of dialysis. Peritoneal dialysis is now accepted as both an important addition to the therapy of renal failure and a useful technique for clinical investigations of solute transfer across a semipermeable membrane.

Simultaneous with the clinical demonstration of the practicability of peritoneal dialysis in cases of impaired renal function were the continued attempts to develop a technique for the extracorporeal dialysis of blood. It was not until 1944 that Kolff (while working under the handicap of the German occupation of his native Holland) devised the first workable artificial kidney[4] by utilizing cellophane sausage casing as a semipermeable membrane through which the patient's arterial blood, with heparin added to retard clotting, was circulated. The blood-filled cellophane tubing was wrapped around a rotating drum which dipped into a 100-liter dialysis bath. Exchange of solute and water was effected prior to the return of the blood to a convenient vein. Shortly after World War II, rotating-drum artificial kidneys (with minor modifications of the prototype) were evaluated at several centers in the United States. Merrill[5] and Schreiner[6] at midcentury collected series of cases demonstrating the effective and often lifesaving use of hemodialysis in the treatment of acute renal failure and certain drug overdosage.

Later modifications of the instrument of hemodialysis were aimed at lessening the burden of preparation of the unit and reducing the size of the blood compartment with the purpose of reducing the cost and hazards of priming with blood. The size of the apparatus necessary to effect hemodialysis was considerably diminished by winding two lengths of cellophane tubing supported by plastic window screening around a beer can to produce the now well known twin-coil artificial kidney. A disposable coil unit for this type of dialyzer has been commercially available for a decade. The need for blood priming in and pumping through the large-volume high-resistance twin-coil unit led to the search for lower-volume, low-resistance dialyzers, the most efficient of which is the Kiil parallel-flow artificial kidney. Among the 300 artificial kidneys estimated to be currently in use in the United States can be found rotating drums, twin coils, and parallel-flow Kiil dialyzers. In this report, examples of several of the many applications of dialysis therapy on a medical service will be illustrated.

Peritoneal Dialysis

Peritoneal dialysis can be performed by a specially instructed nurse after the abdominal puncture wound is made and the apparatus is properly set in operation. Improved abdominal access trocars and inexpensive, disposable, small-diameter nylon catheters permit the insertion of the dialysis cannula under local anesthesia, in the patient's room. After the abdominal wall is shaved and disinfected, a one-centimeter circular area approximately one third of the distance between the umbilicus and pubis is infiltrated with one-per-cent procaine. A number 11 knife blade is used to make a three to five-millimeter skin incision in the anesthetized area through which a 14F trocar is inserted into the abdominal cavity. A nylon catheter is introduced through the trocar, the trocar is removed, and the catheter taped to the abdominal wall. Two liters of dialysate, warmed to body temperature, are allowed to run into the abdominal cavity by gravity flow during a ten to twenty-minute period. After an equilibration time of approximately twenty minutes the fluid is drained into a collection bottle by gravity flow. When indicated, removal of excess fluid from the patient can be accomplished by increasing the osmolality* of the dialysate. An increase in the glucose concentration of the dialysate from 1.5% to either 4.25% or 7% will cause an increase in the return volume of as much as three liters for each two liters instilled. The entire cycle of inflow, equilibration and drainage can be completed in one hour, at which time two liters of fresh dialysate are introduced into the peritoneal cavity and the cycle is repeated. At a flow rate of two liters per hour peritoneal urea clearances of 15 to 25 milliliters per minute are obtained. A

24-hour dialysis at a flow rate of two liters per hour will usually result in a blood urea nitrogen of half the predialysis level.

Acute Tubular Necrosis

Case 1 illustrates the use of peritoneal dialysis in renal failure of undetermined etiology.

Case 1

A twenty-four-year-old negro male heroin addict was hospitalized because of fever and hemoptysis. The patient had allegedly lain unattended in a street for two days after being assaulted. At the time of admission he was poorly responsive and somnolent. Significant findings on physical examination included two + pitting edema of the legs, flatness to percussion of the right posterior chest and tubular breathing and moist rales throughout the posterior right lower lung field. Radiographic examination of the chest disclosed infiltration and cavitation of the right upper lobe and a right pleural effusion.

The white blood count was 22,800 per cu. mm., the hemoglobin 12 gm. per 100 ml.; the urine gave a 1+ test for protein; the sediment contained three red cells and a rare white cell per high power field. The blood urea nitrogen was 200 mg. per 100 ml. and the serum creatinine 9.5 mg. per 100 ml.

During the first hospital day the patient's urinary output was 275 ml. Sequential electrocardiograms showed peaking of the T waves and spreading of the QRS complex indicative of the development of progressive potassium intoxication. Intravenous penicillin therapy, 1.2 million units every four hours, was administered for the pneumonia, and intermittent peritoneal dialysis at a flow rate of two liters per hour was performed during the next two hospital days with a total exchange of 80 liters in 40 hours. By the use of hypertonic dialysis solution with a glucose concentration of 4.25% an excess of 15 liters was removed from the patient with consequent clearing of his edema and a resultant weight loss of 20 pounds. At the end of the dialysis the blood urea nitrogen was reduced to 109 mg. per 100 ml. and the electrocardiogram reverted to normal.

A percutaneous right renal biopsy was obtained on the third hospital day and was consistent with extensive acute tubular necrosis (Figure 1).

Following the peritoneal dialysis the patient developed a sustained diuresis associated with continuing improvement in his renal function. Clinically and radiologically the lung disease resolved during the next three weeks. At the time of discharge on the 43rd day the patient's blood urea nitrogen was 14 ml. per 100 ml. and his endogenous creatinine clearance was 114 ml./minute.

Until the interpretation of the renal biopsy in Case 1 it was not clear whether the patient's diagnosis was acute renal failure due to tubular necrosis, acute glomerulonephritis, or oliguria as a consequence of chronic renal disease.

The over-all mortality from acute tubular necrosis varies from 20 per cent to 80 per cent, depending on the cause. Deaths due to potassium intoxication, intravascular congestion and uremic pericardial tamponade can be prevented by the incorporation of properly timed peritoneal dialysis into the regimen of care for the patient with acute reversible renal failure.

Prolonged Anuria

Peritoneal dialysis can be performed repeatedly in cases of prolonged anuria due to potentially reversible renal failure (Case 2).

Case 2

A 37-year-old Puerto Rican mother of five was hospitalized for the first time because of convulsions, hypertension and pulmonary edema. Ten days previously she had suffered a two-day "bad cold" associated with fever and pharyngitis. Because of confusion, intravascular congestion, and hyperkalemia,

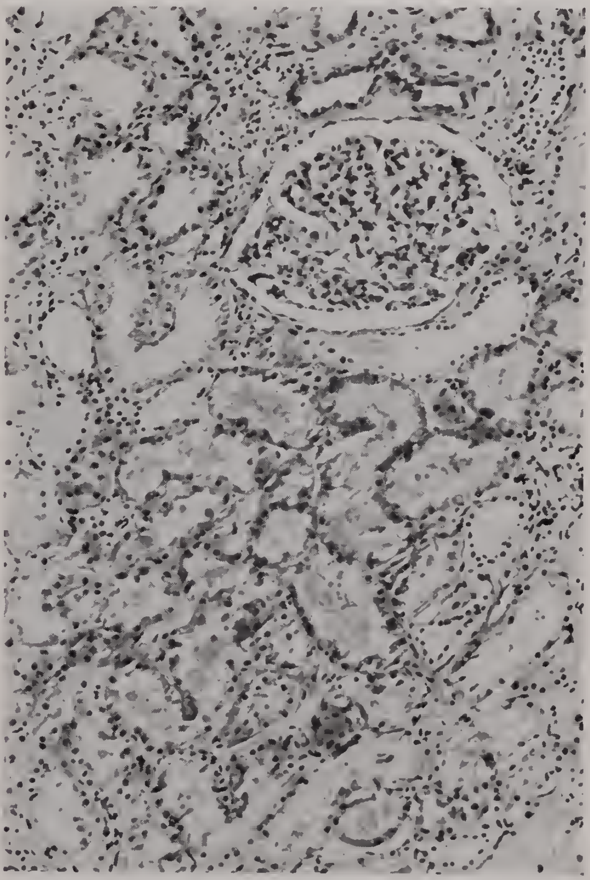

Fig. 1. Case 1 — Acute tubular necrosis. Cortical area of kidney showing tubular epithelium in varying stages of degeneration. Some tubules have an incomplete epithelial covering. Hematoxylin and eosin. X 200.

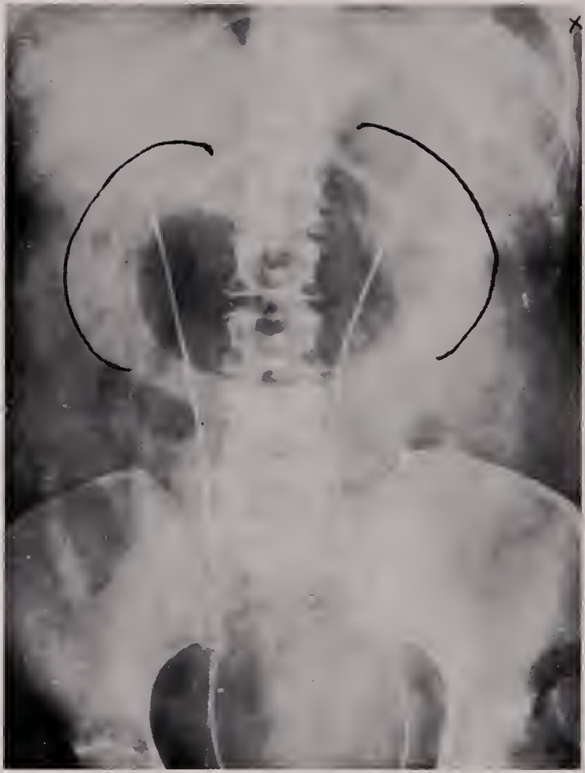

Fig. 2. Case 2 — Both kidneys are swollen and measure 15 cm. in length. The ureters are patent.

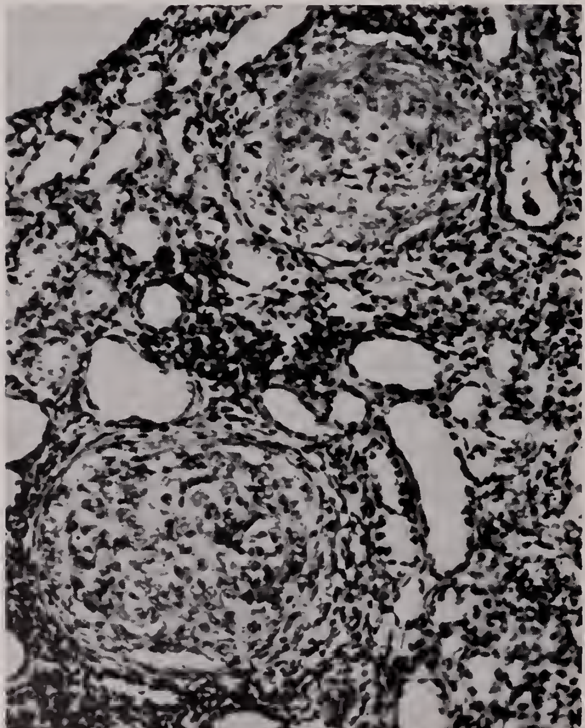

Fig. 3. Case 2 — Acute glomerulonephritis. Two glomeruli showing marked hypercellularity of the tufts with almost complete obliteration of Bowman's space. Hematoxylin and eosin. X 200.

intermittent peritoneal dialysis with hypertonic dialysate was begun shortly after admission. The initial dialysis resulted in a reduction of the blood urea nitrogen from 140 to 75 mg. per 100 ml. and a fall in the serum potassium from 6.6 to 4.2 milliequiv. per liter. On the third hospital day, because the patient was anuric, bilateral ureteral catheterization was performed and patency of both ureters was demonstrated. The tentative diagnosis of post-streptococcal glomerulonephritis was substantiated by the finding of enlarged kidneys, measuring 15 cm. each (Figure 2), an elevated antistreptolysin 0 titer of 833, and a percutaneous biopsy of the right kidney (Figure 3).

Although ambulatory, afebrile and comfortable, the patient remained totally anuric. Three peritoneal dialyses were required to control her uremic symptoms during the first fifteen days of her hospitalization. It was then decided to place the patient on a regimen of weekly peritoneal dialysis in hospital while she remained at home with her family for six days of each week. A 14F nylon catheter was left in the peritoneum and the patient was discharged with instructions to follow a 40-gram protein, 400 mg. sodium, 2,500 calory diet. To increase bowel excretion of dietary potassium 50 grams of a potassium exchange resin and 40 ml. of sorbital were prescribed daily.

For the ensuing five months, though totally anuric and mildly hypertensive, the patient remained at home with her family preparing meals and caring for her children. Active destruction of renal mass continued throughout this period as evidenced by the marked reduction in renal size seen in nephrotomograms taken three months after the onset of illness (Figure 4).

The patient's blood urea nitrogen (Figure 5) and serum potassium (Figure 6) were effectively controlled for five months by weekly peritoneal dialysis, but relentless weight loss (Figure 7) continued until the patient's sudden death at home three days after her last peritoneal dialysis, during the 24th week of her illness. An autopsy was not performed.

Reports of recovery of renal function after as long as 28 days of anuria due to post-streptococcal glomerulonephritis have been confirmed.[7] At what point in the proper management of acute glomerulonephritis is dialysis to be discontinued? Should dialysis be stopped even though the anuric patient is in satisfactory medical condition? How long can peritoneal dialysis be continued without technical failure? These questions are the subject of active investigation and are only partially answerable at this time.

Complications of Dialysis

Protein Loss

Complications have limited the survival of most functionally anuric patients to about six months. Josephson and Friedman detected as much as 1½ grams of plasma protein, principally albumin, per liter of peritoneal dialysate, a quantity difficult to replenish by increased dietary intake of proteins. Boen has infused intravenously the ascitic fluid found at the start of each dialysis and thus limited the protein-wasting. We have infused 25 grams of salt-poor human albumin twice monthly with satisfactory preservation of plasma albumin concentration at 3.5 grams per 100 ml. into a patient now in his sixteenth month of intermittent peritoneal dialysis performed at seven-day intervals.

Peritonitis

The incidence of bacterial peritonitis can be markedly reduced by strict attention to aseptic technique and the use of a fresh puncture for each dialysis. Antibiotics are added to the dialysate only when the signs of peritonitis are present and are changed to suit the sensitivity of any cultured organism.

It is obvious that the regular cycling of two liters of dialysis fluid per hour over any several days can prove a burdensome chore. In order to lessen the labor of peritoneal dialysis and increase its efficiency, automatic machines have been devised by Boen[8] and McDonald.[9] The McDonald peritoneal dialysis apparatus supplants gravity flow by pumped inflow and outflow, achieving exchanges as high as eight liters per hour with urea clearances of 35 to 50 milliliters per minute.

Improved techniques for performing peritoneal dialysis and conserving plasma proteins will result in a decreased morbidity and mortality due to this procedure.

Hemodialysis

Hemodialysis is a more complex procedure than peritoneal dialysis. Connections must be established between the dialysis apparatus and the patient's blood vessels. Because of the necessary vascular surgery, and because rapid changes in the patient's clinical state are effected by this more efficient procedure, a team of physicians and nurses is required to care for the acutely-ill patient subjected to hemodialysis.

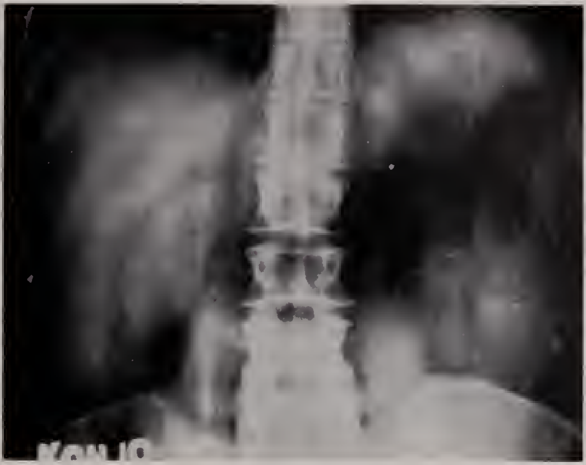

Fig. 4. Case 2 — Three months after the onset of acute glomerulonephritis the kidneys are reduced in size to 7 and 8 cm. in length.

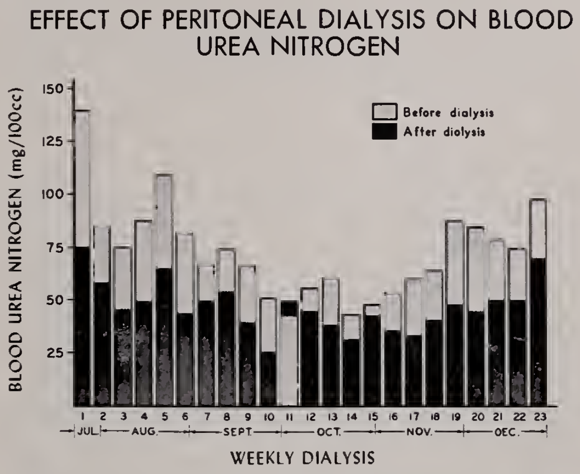

Fig. 5. Case 2 — The patient's blood urea nitrogen was generally maintained between 50 and 100 mg. per 100 ml. throughout the five months of dialysis.

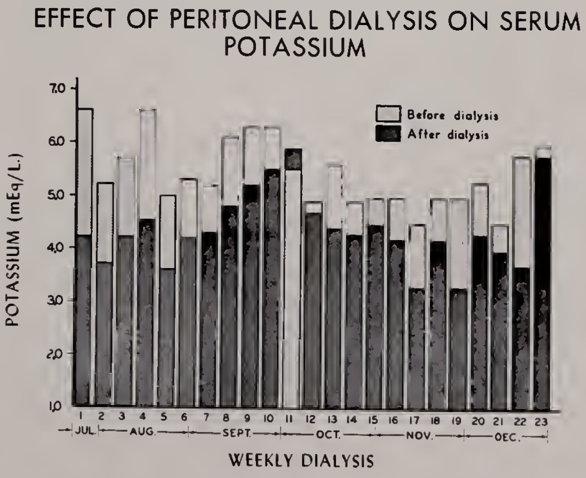

Fig. 6. Case 2 — Prior to each weekly dialysis hyperkalemia was present.

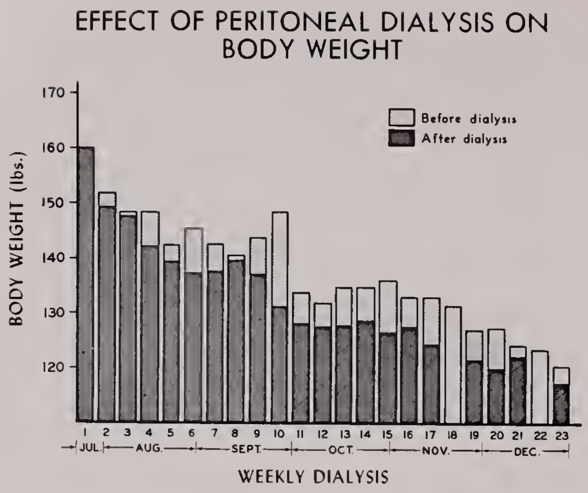

Fig. 7. Case 2 — Progressive weight loss of 40 pounds in five months of peritoneal dialysis was related to restricted protein ingestion and protein wastage in the dialysate.

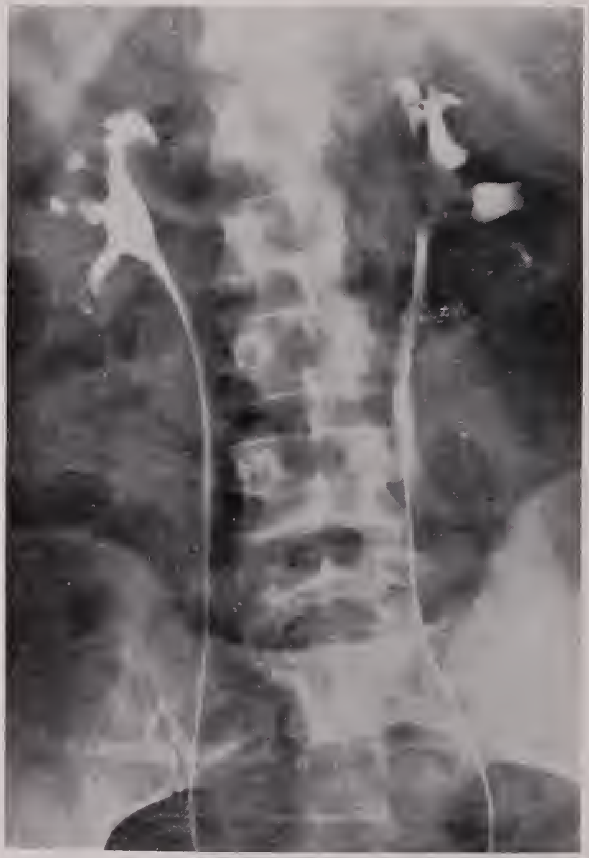

Fig. 8. Case 4 — Both kidneys are reduced in size. They have distorted collecting systems and thin parenchyma consistent with chronic pyelonephritis.

Drug Intoxication

One of the most successful applications of hemodialysis has been in the treatment of drug intoxications. The list of dialyzable poisons is constantly growing and has been most recently revised by Maher in 1964.[10] Case 3 is an example of the effective use of hemodialysis to treat a patient who ingested an overdose of a dialyzable sedative.

Case 3

A twenty-two-year-old unemployed white male stock clerk was transferred from another hospital approximately six hours following the ingestion of twenty-seven 0.5 gm. tablets of glutethimide (Doriden). The patient was comatose and had neither the corneal nor gag reflex. During the initial two-hour period of observation his coma deepened and he became hypotensive with a blood pressure of 80 systolic and 20 diastolic. A double-lumened nylon catheter was passed through the right long saphenous vein into the inferior vena cava yielding a blood flow of 300 ml./minute. Hemodialysis was performed through a Kolff twincoil artificial kidney primed with two units of bank blood.

The patient's response to hemodialysis was rapid. By the third hour his corneal and gag reflexes had returned and by the fifth hour flailing movements of his extremities were present. At the conclusion of six hours of hemodialysis the patient was sufficiently alert to give his own medical history. Thereafter his recovery was uneventful, and in collaboration with a consulting psychiatrist the patient was discharged on the fourth hospital day to the outpatient clinic.

Uremia

Hemodialysis will produce improvement in the signs and symptoms of uremia, whether due to either acute or chronic renal failure. Until the development by Scribner of a method for indwelling long-term arterial and venous cannulation, however, the number of hemodialyses which could be performed on patients was limited by the availability of peripheral blood vessels. Scribner devised indwelling silicon-elastic and teflon cannulas which allowed for repeated use of the same artery and vein over months or years.[11] Arterial blood is externally shunted to a vein in the arm or leg without the necessity for the use of anticoagulants except during periods of hemodialysis. Case 4 is a patient who has had such a shunt in place for thirteen months.

Case 4

A 32-year-old white housewife was hospitalized at the Kings County Medical Center for the first time in October 1964 because of azotemia and hypertension. Her only pregnancy eight years earlier, although complicated by hypertension and edema, produced a full-term healthy son. Episodic back pain, fever and dysuria interrupted her work as a bookkeeper with increasing frequency during the next few years and culminated in sustained nausea, vomiting, somnolence and oliguria, which necessitated her admission to another hospital in June of 1964. A 48-hour peritoneal dialysis performed at that time induced a partial remission and the patient was discharged. She remained at home, however, suffering from nausea and lethargy until a convulsion caused a second hospitalization in August 1964. Therapy consisted of short-term peritoneal dialysis with hypertonic dialysate which resulted in considerable diminution in the patient's nausea and an improved sensorium. She then remained home for seven weeks until the onset of convulsive seizures and pulmonary edema required a third hospitilization. Following an uncomplicated peritoneal dialysis with remission of her uremic symptoms the patient was transferred for further therapy.

Physical examination at the time of admission disclosed a drowsy, cooperative woman appearing acutely and chronically ill. She was deeply pigmented and had 3+ pitting edema of the legs and sacrum. The blood pressure was 180 systolic, 108 diastolic. Her hemoglobin was 6.8 gm. per 100 ml.; the white blood count was 10,800 cu. mm. with a normal differential count. A urinalysis revealed 2+ protein, 0 to 1 red blood cells, and 12 to 15 white blood cells per high power field. Two urine cultures grew enterococcus organisms. Both kidneys were contracted with marked loss of cortical tissue consistent with chronic pyelonephritis (Figure 8); a percutaneous biopsy of the right kidney confirmed this diagnosis (Figures 9, 10). It was apparent from the endogenous creatinine clearance of 1.6 ml./ minute that the patient's residual renal function was insufficient to sustain life.

Accordingly, a silastic-teflon arterial venous shunt was inserted into the left radial artery and vein to allow for repeated hemodialysis (Figures 11, 12). The patient has been maintained for thirteen months by a program of twice weekly night-time hemodialysis utilizing a low pressure, nonpriming Kiil parallel-flow artificial kidney. Since her discharge in December 1964 she has resumed her household responsibilities and has been clinically well, with a gradual weight gain of 17 pounds. Her therapeutic regimen consists of a 40-gram protein 400 mg. sodium 2,500 calorie diet with no other medications. Her urine output varies from 50 to 100 ml. daily.

Table 1 lists this patient's pre- and postdialysis blood chemical values for a typical eleven-hour hemodialysis.

Complications

Intermittent hemodialysis substitutes for only a few of the complex functions performed by the healthy kidney. The rehabilitated patient remains anemic and colored by urochrome pigment in his skin. He may develop arthritis, peptic ulceration, peripheral neuropathy or secondary hyperpara-

thyroidism. His requirement for blood transfusions exposes him to inoculation with the virus of hepatitis.

Case 5

A 43-year-old white married businessman developed end-stage renal failure and anuria due to chronic glomerulonephritis. For five months, while receiving twice weekly hemodialysis with a Kolff twin-coil artificial kidney primed with bank blood, he remained out of hospital and able to run his dress factory. He was normotensive and had regained eight pounds when, during the sixth month of dialysis, he contracted fulminant hepatitis which necessitated hospital readmission. Progressive jaundice and a clouded sensorium were not altered by either corticosteroid therapy or an eight-hour hemodialysis. The patient died two days later while in liver coma. Autopsy examination showed extensive necrosis of the liver consistent with the diagnosis of viral hepatitis.

Comments and Conclusions

Despite the medical and psychological limitations of a life dependent on a machine, the patient subjected to chronic intermittent hemodialysis has much more than just a gloomy alternative to death. The majority of patients return to their jobs, schools or homes on a near full-time basis.

Approximately 200 patients with "end stage" uremia are receiving this form of therapy today.

Whether the treatment of choice for chronic renal failure a generation from now will involve the transplantation of a cadaver or animal kidney, or the insertion into the abdomen of a small artificial kidney made of a plastic yet to be devised, is highly speculative. What is clear is that the physician with an interest in uremia can more hopefully expect an increasingly brighter prognosis for his patients.

Acknowledgments

The dialysis unit at the Kings County Medical Center is a combined venture of the medical and urology services. Dr. R. Keith Waterhouse and Dr. Harold McDonald, Jr., collaborated in the care of the patients reported, Dr. Gerald E. Thomson in the studies of the patients subjected to hemodialysis, and Dr. Stanley Minkowitz with the pathology of the renal biopsies.

Megaloblastic Anemia of Infancy

- Response to a
- Minimal Dose
- of
- Pteroylglutamic Acid

MARGARET G. ROBINSON, M.D.*
Brooklyn, New York

THE DAILY minimal requirement and the minimal therapeutic dose of folic acid are unknown. The usual therapeutic dosage ranges from 0.4 to 10 mg. per day. A few workers have used minute doses of the order of 25 to 50 ug. of folic acid daily to determine the minimal therapeutic dose for adults.[1-4] Although the response to therapy was delayed, these minute doses have cured folic-acid deficiency. Since the minimal therapeutic dose is close to the minimal daily requirement, Zalusky and Herbert,[1] on the basis of one case report, have suggested that the minimal daily requirement of adults for the free form of folic acid is probably of the order of 50 to 100 ug. per day.

No similar work has been performed on infants. We have attempted to determine the probable range of the minimal therapeutic dose and, indirectly, the minimal daily requirement of folic acid in a five-month-old infant. The therapeutic response obtained with the daily administration of 50 ug. of pteroylglutamic acid while the child was maintained on a folic-acid-free diet would indicate that the minimal therapeutic dose and minimal daily requirement of the free form of folic acid for infants are equal to or less than 50 ug. per day.

Methods

Standard methods were used for the determination of complete blood counts every three to four days.[5] Reticulocyte counts were made daily, using brilliant cresyl blue. Bone-marrow aspirates were obtained from the tibia or the anterior iliac crest. Folic-acid plasma clearance tests were performed by the method of Herbert and Zalusky[6] by giving 15 ug. per kg. body weight of folic acid

intravenously. Serum was obtained at 15 and 30 minutes after the intravenous injection and assayed microbiologically using Lactobacillus casei by the aseptic method of Herbert et al.[7]

Case Report

An 11-week-old premature, negro female infant was admitted to Kings County Hospital for diarrhea of five days' duration. Nonprojectile vomiting and fever (39.4°C.) had begun two days prior to admission. Her birth weight was 2.5 kg. During the first month of life she was treated for an omphalitis and an acyanotic heart disease. At eight weeks of age she received two weeks of penicillin therapy for a right middle lobe pneumonia. Her diet consisted of 15 oz/day of Similac® formula and Tri-vi-Sol® 0.6 cc. daily (containing 60 mg. ascorbic acid). The family history was noncontributory.

Physical Findings

The physical examination showed a moderately dehydrated infant weighing 3 kg. Her temperature was 37°C; respiratory rate, 44/min.; pulse, 160/min. There was a grade 3 systolic murmur at the left of the sternum, maximal in the third intercostal space and radiating into the axilla. The patient was lethargic. The remainder of the physical examination was within normal limits.

The hemogram showed a hemoglobin of 8.5 gm% with a leukocytosis (Table 1). Stool cultures were positive for enteropathogenic E. coli, type 0111 B4. The admission chest roentgenogram showed only increased pulmonary markings.

During the next 12 weeks she had six bouts of diarrhea treated with neomycin and colymycin, a purulent conjunctivitis treated with neosporin ophthalmic ointment, and a diffuse pneumonia involving the entire right lung and left upper lobe, which was treated with penicillin. Intravenous fluid therapy was used to correct hydration and acidosis. Between each episode of diarrhea her diet consisted of Similac® formula and Tri-vi-sol® 0.6 cc. daily.

Diagnostic Studies

At 23 weeks of age during her sixth episode of diarrhea she developed increasing pallor and unresponsiveness to therapy. Examination of her blood showed a hemoglobin of 5.8 gm% (Table 1). Some macrocytes, a rare hypersegmented neutrophil and a few nucleated erythrocytes with minimal megaloblastic changes were seen on the peripheral blood smear (Figure 1). Following a transfusion of 40 cc. of whole blood her hemoglobin was 7.2 gm% and her reticulocyte count, 0.4%. The pretherapy bone marrow was megaloblastic (Table 2 and Figure 2). A folic-acid plasma clearance study performed on the first day of therapy using a total dose of 54 ug. of pteroylglutamic acid was abnormally rapid (Table 3). A diagnosis of folic-acid deficient megaloblastic anemia was made.

Therapy

She was given 50 ug. of folic acid intramuscularly every day. During the first 10 days of folic-acid therapy the child was being hydrated with intra-

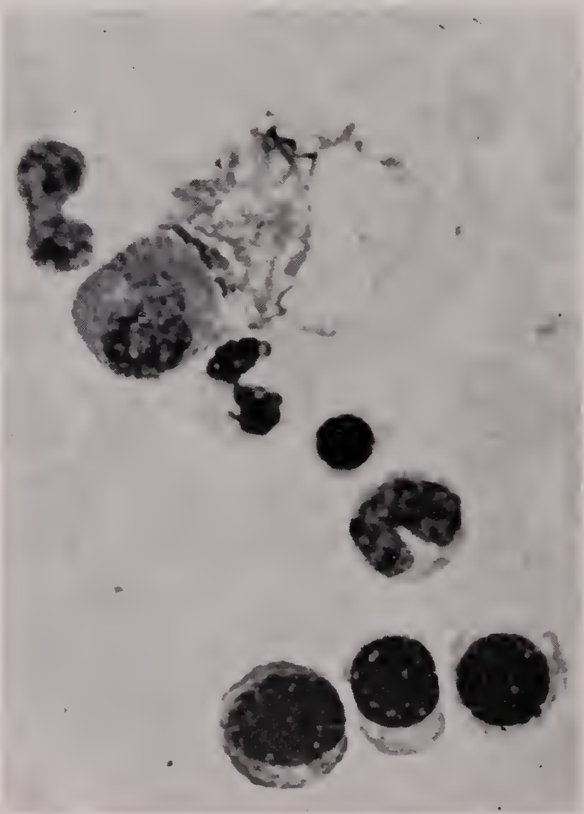

Fig. 4 — Bone marrow on 22nd day of therapy showing the typical polychromatic normoblasts (x 1000).

venous fluids and oral electrolyte solution. No formula, solid foods or supplementary vitamins were given. A peak reticulocyte response of 9.6% was reached on the sixth day of therapy (Figure 3). On the seventh day the bone marrow still showed minimal megaloblastic changes in the erythroid series and giant metamyelocytes (Table 2). A folic-acid plasma clearance test on the 10th day of therapy showed borderline normal values (Table 3).

Between the 10th and 20th days of folic acid therapy her diet consisted of 300 mg. ascorbic acid and 500 cc. of Similac® daily, with no evidence that the vitamin C influenced the reticulocyte count (Figure 3). Her hemoglobin rose to 9.5 gm% by the 20th day. A bone marrow performed on the 22nd day of folic-acid therapy demonstrated a normoblastic marrow (Table 2 and Figure 4). Her red cell count rose from 2,630,000/cu. mm. on the first day of therapy to 3,800,000/cu.mm. on the 38th day. The dietary and parenteral folic acid were increased to 100 and 200 mg./day on the 20th and 28th days of therapy respectively without any further rise in reticulocytes or hemoglobin (Figure 3).

Because her peripheral blood smear showed mild hypochromia, oral iron supplements to the diet were recommended. She failed to return to clinic following her discharge. At 13 months of age when she was readmitted for pneumonia and congestive heart failure she had an iron deficiency anemia (Table 1). Following a total dose of 300 mg. of elemental iron given intramuscularly, her hemoglobin at 14 months of age was 12.0 gm% and her peripheral blood smear was normocytic and normochromic.

Discussion

In the past, *differentiation of folic-acid deficiency from vitamin B_{12} deficiency* has been made by therapeutic trial, using 0.4 to 10 mg. of folic acid. The use of a therapeutic trial for differentiating these two forms of megaloblastic anemia has a serious disadvantage. By mass action, folic acid given in daily doses of 1 to 10 mg. will convert to normal a megaloblastic marrow due to vitamin B_{12} deficiency. Only vitamin B_{12} will prevent or arrest the development of the neurologic changes associated with pernicious anemia. The daily administration of even as small a daily dose as 0.4 mg. of folic acid can revert the megaloblastic marrow of vitamin B_{12} deficiency to normal without preventing the central nervous system complications of pernicious anemia.[8]

One method of preventing the masking of a pernicious anemia by the use of folic acid would be to treat all patients who have megaloblastic anemia with both folic acid and vitamin B_{12}. Since pernicious anemia is a life-long condition this would necessitate continuous therapy with vitamin B_{12} in all cases of megaloblastic anemias. A second and more practical method to solve this problem would be to find a small enough dose of folic acid that would be just sufficient to cure folic-acid deficiency without altering the hematological picture in vitamin B_{12} deficiency.

Because of this danger of *masking a vitamin B_{12} deficiency with the usual therapeutic dosages of folic acid,* a few workers have attempted to find the minimal therapeutic dose of folic acid. Using 25 to 50 ug./day, these workers have successfully treated folic-acid-deficient megaloblastic anemia associated with anticonvulsants, scurvy, sprue and pregnancy in adults.[1-4] All the patients except one received additional folic acid in their diet. The patient reported by Zalusky and Herbert[1] responded to the daily administration of 50 ug. of pteroylglutamic acid while being maintained on a folic-acid-free diet. The delayed but complete responses to these minute dosages of folic acid would indicate that the minimal therapeutic dosage was in the range of 50 to 100 ug. per day and that the minimal daily requirement was equal to or less than this for adults. No similar work has been done on infants.

To determine the range of the minimal therapeutic dose and the range of the daily minimal requirement of this vitamin for infants, we administered 50 ug./day of pteroylglutamic acid parenterally while maintaining our five-month-old patient on a folic-acid-free diet. The diagnosis of folic-acid-deficient megaloblastic anemia was made in this patient by the finding of a megaloblastic marrow and an abnormally rapid folic-acid plasma clearance test. During the first 22 days of therapy the patient's reticulocyte count reached its peak of 9.6%, her folic-acid plasma clearance test returned to normal and her bone marrow became normoblastic. Her hemoglobin and red cell count rose to normal levels for a premature infant of her age who has not been on supplementary iron. A subsequent increase of dietary and parenteral folic acid to 100 and 200 ug. daily and the administration of ascorbic acid did not result in any further increase in reticulocytes or hemoglobin, indicating that a complete therapeutic response was obtained with the smaller dose of folic acid.

The usual daily dose of 0.4 to 10 mg. of folic acid converts a megaloblastic marrow to normal in 24 to 48 hours. The second marrow aspirate obtained on the seventh day of therapy still showed minimal megaloblastic changes. The delay response in this infant would suggest that the dosage of 50 ug./day of pteroylglutamic acid was close to the minimal therapeutic dose for infants. Although the majority of megaloblastic anemias seen in infants result from folic-acid deficiency, a few are due to vitamin B_{12} deficiency. Whenever the folic-acid plasma clearance test is not available for definitive diagnosis of folic-acid deficiency, we would recommend that not more than 50 ug. of folic acid be administered daily for the therapeutic trial of any suspected folic-acid deficiency in infants. The use of this dosage ought to prevent the masking of a vitamin B_{12} deficient megaloblastic anemia.

Since the daily *minimal requirement of free folic acid* for infants can not exceed the minimal therapeutic dosage, it must be equal to or less than 50 ug./day. Approximately 95% of the dietary folic acid is in the bound or conjugated form,[4,9] and only a minute fraction of this bound folic acid can be converted to free folic acid.[10] Since only free folic acid can be absorbed from the intestinal tract and since the rate of absorption of free folic acid in infants is unknown, the requirements of total (bound and free) folic acid in the diet is unknown.

Summary

A five-month-old premature infant with chronic diarrhea and pneumonia developed megaloblastic anemia due to folic-acid deficiency. Daily therapy with 50 ug. of pteroylglutamic acid converted her magaloblastic bone marrow to normal with a rise of reticulocytes, red cells and hemoglobin. Because the response to therapy was delayed, this dose of 50 ug. is probably in the range of the minimal therapeutic dosage of folic acid.

Since 50 ug. of pteroylglutamic acid administered daily resulted in a complete cure of the infant's megaloblastic anemia, the daily minimal requirement of free folic acid is equal to or less than this amount.

Acknowledgment

We are indebted to Miss Janet Bowne and Mr. Vernon Delgado for performing the hematological determinations.

TUBOVASCULAR RENAL SYNDROME

(Lower Nephron Nephronis — Bywater Syndrome)

Oliguria or anuria may be the first evidence of this symptom complex. Associated with this there is a rapid increase in the retention of non-protein nitrogen, creatinine, potassium and inorganic phosphorus.

This type of impaired renal function may follow shock due to trauma or hemorrhage, crushing injuries, post-transfusion reaction, or it may be from the toxic effect of chemical nephrotoxins. It has been observed to follow blackwater fever, septic abortion, cholera, yellow fever, Weil's disease or war injury and is thought to be due to renal ischemia.

Unless the urinary secretion is restored, death usually occurs on about the eighth day. It may, however, be reversible and in those who do survive, there may be a post anuric period of several weeks with impaired function, nitrogen retention and diminished concentration of the urine.

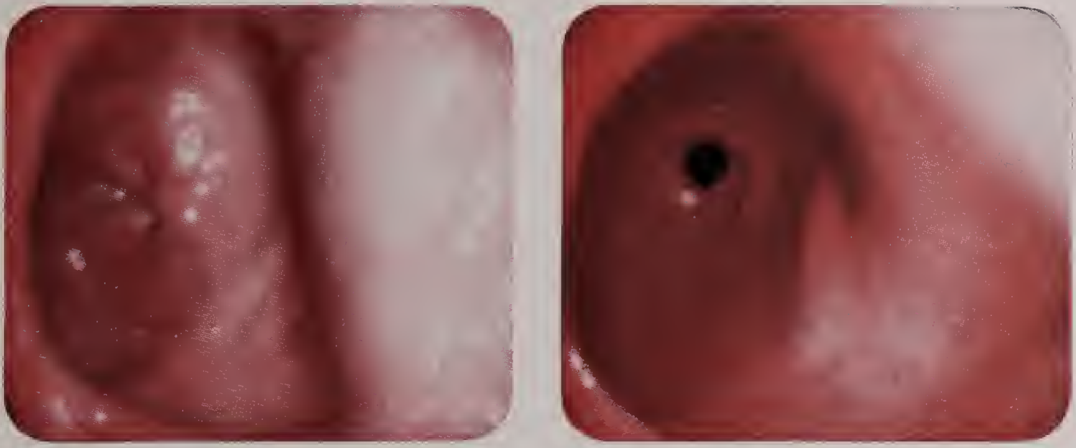
Derivatively Speaking

Ficus: from Latin *ficus,* a fig

If men use their liberty in such a way as to surrender their liberty, are they therefore any less the slaves? — Herbert Spencer, 1851

Mankind are poor, transitory things; one day in life, and the next turned to ashes. Therefore manage this minute wisely and part with it cheerfully; and like a ripe fruit, when you drop, make your acknowledgements to the tree that bore you.

— Marcus Aurelius



Intragastric photography studies[1]

A/ E. B., male, age 48. Normal antral contraction. Pyloric opening is not seen. It is difficult to differentiate a deep prepyloric contraction from a "pyloric fleurette" or true pylorus.

B/ Same subject after 6 mg. of propantheline bromide intravenously; antral contractions ceased. The pyloric orifice remained open and was easily identified. Better visualization of the antrum was also obtained.

Now you can see Pro-Banthīne® at work

(propantheline bromide)

Pro-Banthīne is so effective in anticholinergic action that it may be employed in visualizing the entire pyloric region.

In addition to the intragastric photographs, cinegastroscopic studies[2] have demonstrated graphically not only its effectiveness but the superiority of Pro-Banthīne over belladonna alkaloids.

Pro-Banthīne produced complete cessation of gastric, antral and pyloric motor activity with a dose of 6 mg. intravenously. This is approximately one-third the usual oral dose of 15 mg.

Atropine at full normal dosages did not produce such cessation. It required double the usual oral dose of atropine, 0.8 mg. intravenously, to duplicate the aperistaltic action of Pro-Banthīne. This dose of atropine produced pronounced discomfort and tachycardia with ventricular rates as high as 150 per minute.

It is this pharmacologic superiority of Pro-Banthīne which has made it the most widely prescribed anticholinergic in such conditions as peptic ulcer, functional hypermotility, irritable colon, pylorospasm and biliary dyskinesia.

Dosage—The maximal tolerated dosage is usually the most effective. For most *adult* patients this will be four to six 15 mg. tablets daily in divided doses. In severe conditions as many as two tablets four to six times daily. Pro-Banthīne (brand of propantheline bromide) is supplied as tablets of 15 mg., as prolonged-acting tablets of 30 mg. and, for parenteral use, as serum-type ampuls of 30 mg.

Side Effects and Contraindications—Urinary hesitancy, xerostomia, mydriasis and, theoretically, a curare-like action may occur. The drug is contraindicated in patients with glaucoma or severe cardiac disease.

An Expanding Appreciation

ONLY RARELY do different departments of the same medical faculty contribute as a unit to provide an issue for national publication. Although there are some well-known journals which are products of individual medical centers, most of us contribute to journals within our respective disciplines and for readers in those disciplines. As a result, we all have a tendency to be unaware of current work in progress in other departments within our own medical centers. The opportunity

to fashion this issue of MINNESOTA MEDICINE has proven highly gratifying to us. The call for ideas and contributions has made us acutely aware of the diversity and caliber of the current work in progress in the clinical departments here. In retrospect, the only painful aspect of the participation has been the necessity for selection of papers because of limitations of space. The contributing editors are grateful that this activity has provided us occasion to browse through some of the work in other medical areas than our own at this Medical Center. We also have come to appreciate to what a degree there is not only a willingness but an eagerness to achieve our ends by competitive and yet congenial effort.

We wish to express our very real appreciation to the Editor-in-Chief of MINNESOTA MEDICINE for his very generous invitation to participate with him in this manner.

Clarence Dennis, M.D.
Marvin L. Gliedman, M.D.
Brooklyn, New York

State University of New York Downstate Medical Center

IN THIS special issue of MINNESOTA MEDICINE I would like to express the pleasure and pride the Downstate Medical Center Faculty and Administration take in the opportunity offered here to report to associates in another part of the country some of the many activities in progress at our rapidly expanding Medical Center in Brooklyn.

We in Brooklyn feel strong ties to our associates in Minnesota. The editors of this special issue — Drs. Clarence Dennis and Marvin Gliedman — both have been associated with the University of Minnesota. Dr. Dennis, who came to Downstate in 1951 as Professor and Chairman of Surgery, was associated with the University of Minnesota for 16 years. He received his M.S. in physiology and his Ph.D. in surgery, took his internship and residency training in surgery there, and served on the faculty for 12 years. Dr. Gliedman, a graduate of Downstate, took his surgical internship at Minnesota and is now a Markle Scholar at State University of New York.

Another department chairman — Dr. Harry Mellins in Radiology — spent four years on the Minnesota faculty. Drs. Karl Karlson, Irving Enquist, and Harry Kaplan, all in the Department of Surgery, are Minnesota medical graduates. Drs. Karlson, Charles Fries, and Irving Enquist, in Surgery, interned at Minnesota; Dr. Karlson also received his Ph.D. there. Many others with Minnesota backgrounds, some of them contributors to this issue, have joined the State University of New York.

On the other side of the picture, we are pleased that a number of our graduates have gone to the University of Minnesota. One of our graduates and interns, Dr. Eugene Bernstein, is now a Markle Scholar with Dr. Owen H. Wangensteen at Minnesota.

Great progress has been made at the Downstate Medical Center since it became part of the State University of New York in 1950. Enrollment in the College of Medicine was 110 students in 1950; this year the first class of 200 was admitted. A Graduate Educational Program to train teachers and researchers in the basic medical sciences was established in 1956 and now has an enrollment of 60. The number of full time faculty members has been more than trebled. Affiliations with community hospitals have been increased and fortified. A new Basic Sciences Building was opened in 1956 providing modern facilities for research and teaching in the six basic sciences. This year two new residence halls for students and their families were opened next to the Basic Sciences Building.

Meanwhile, construction is advancing on a new University Hospital, scheduled to open in 1966. This building is connected to the Basic Sciences Building by a clinical sciences wing. The Hospital will have 350 beds and facilities for 110,000 outpatient visits a year, as well as facilities for research in the clin-

ical departments, which will adjoin each department's nursing unit. Plans for the future include a College of Nursing to be opened in conjunction with the Hospital, and eventually a College of Health Related Services. Curricula in occupational and physical therapy, to be part of the latter College, will begin in the fall of 1965. The Medical Center Library has been merged with the Library of the Academy of Medicine of Brooklyn, one of the largest medical libraries in the country, and the entire collection will be housed in the Basic Sciences Building at Downstate.

As the only Medical school in Brooklyn and Long Island — an area with approximately 7,000 physicians and a population of four and half million — the Downstate Medical Center is becoming a center for meetings and educational activities of professional organizations and hospitals and the focal point and coordinating agency for postgraduate courses and scientific symposia and conferences in the area. Many medical organizations now hold their regular meetings at Downstate. Furthermore, the Center, in cooperation with the Kings County Medical Society and other medical organizations, offers a varied program of postgraduate courses throughout the academic year. The Medical Center and the various departments are also increasingly acting as host to medical and scientific organizations, groups, and individuals from other parts of the country and the world. Visitors are cordially welcome at Downstate and we hope that this special issue will encourage many of our Minnesota colleagues to pay us a visit.

Robert A. Moore, M.D.*

Annotation on Life

THE EMOTIONAL argument for therapeutic abortion was recently dramatized in Life Magazine, June 4, 1965. The threat of congenital malformations occurring in the fetuses of mothers infected with rubella virus early in pregnancy has seldom been so poignantly illustrated. Anticipation of the major epidemic of congenital malformations which will follow the present rubella epidemic has caused many persons to question the 20th century validity of 19th century laws on therapeutic abortions.

The plight of mothers carrying deformed fetuses was newsworthy during the Thalidomide scare but, because of Dr. Frances O. Kelsey's careful work, had minimal emotional connotation for the American people. The present rubella epidemic, however, provides an emotional as well as a real threat, for few pregnant women are absolutely sure that they have not had rubella and can be completely isolated from contact with children who have the disease.

The pregnant woman who is aware of the threat realizes that she has a substantial chance to have a deformed infant if she acquires clinical rubella. She may not know that exposure alone, without clinically evident rubella, carries a significant risk. On the other hand, as several other viruses can produce a clinical picture and skin rash which closely resemble rubella, she may be falsely alarmed by a mild fever and skin rash. A new complement fixation test, developed at the National Institutes of Health and available at the U. S. Communicable Disease Center in Atlanta at the request of state health departments, will tell within 24 hours whether or not a person has had a recent rubella infection. If the test is negative, uncertainty will be resolved for the pregnant mother, but if the test proves recent rubella infection, uncertainty, doubt and probably fear will be established.

She will be concerned about what could happen to her child. Any of the following anomalies could occur: auditory sac absence

**to help relieve pain
in common
anorectal disorders**

"non-caine"

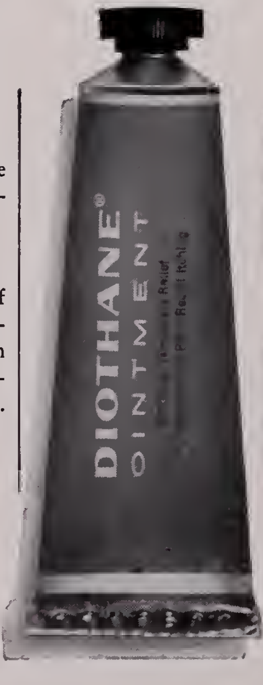
Diothane®

Diothane—with its chemically distinct "non-caine" anesthetic agent diperodon—provides effective temporary topical anesthetic and emollient actions for soothing relief of anorectal pain. Anesthetic activity is effective and relatively prolonged; sensitization is infrequent. Reports to Merrell on 1,500 patients treated pre- and postoperatively with Diothane Ointment, indicate only 22 developed local skin reactions. Reactions to Diothane have been burning or stinging sensations and a few cases of allergic manifestations. An additional advantage: Diothane Ointment and Suppositories are mildly antiseptic. Prescribe or recommend either form... both are now available.

DIOTHANE OINTMENT

COMPOSITION:
diperodon 1.0%; oxyquinoline benzoate 0.1% in a special ointment base.

INDICATIONS:
Provides temporary palliation of pain that may result from hemorrhoidectomy and from common anorectal disorders such as hemorrhoids, anal fissures, pruritus ani.



CHILL
PULL APART

DIOTHANE SUPPOSITORIES

COMPOSITION:
Each suppository, weighing approximately 2.6 Gm., contains diperodon 1.0%; urea 10.0%; oxyquinoline benzoate 0.1% in a special hydrophilic suppository base. A unique shape keeps the suppository in intimate contact with mucous membranes.

INDICATIONS:
Provide for temporary palliation of pain caused by hemorrhoids and pruritus ani.

or defective formation, buphthalmos, cataracts, cleft palate, cryptorchidism, dental defects, deafness, genu valgum, glaucoma, hydrocephalus, harelip, hypospadias, heart defects, hepatosplenomegaly, intrauterine growth retardation, Horner's syndrome, hemiparesis, hepatitis, imperforated anus, lens absence, degeneration, hypoplasia or necrosis, metaphysitis, mongolism, microcephaly, mental retardation, myelocele, obliteration of bile ducts, pyloric stenosis, strabismus, spastic diplegia, spina bifida occulta, thrombocytopenic purpura, talipes and umbilical hernia. Some of these defects are life-threatening and contribute to a significant increase in neonatal mortality; many, however, are mild and curable. Other defects are severely crippling.

The pregnant woman will be concerned about the likelihood of something happening to her child. The incidence of malformations after rubella infection is not constant; it depends upon the time in pregnancy when the infection occurs, and it decreases with the duration of pregnancy. Retrospective studies, correlating rubella infection with malformations, disclosed that between two and four weeks after the last menstrual period almost 60% of fetuses were deformed, between five and eight weeks about 35%, between nine and 12 weeks about 15%, and between 13 and 16 weeks about 7%. The over-all risk for the first 16 weeks was 21%. The risk during the first two weeks of pregnancy was undetermined; it may have been higher or lower than 60%. The risk after 16 weeks (also unknown) may have become very small. These figures have a corollary value and a positive side: the chances of a child not being affected when the mother has rubella increases with duration of pregnancy. These chances appear to be about 40% if the infection occurs between two and four weeks after the last menstrual period, 65% between five and eight weeks, 85% between nine and 12 weeks and 93% between 13 and 16 weeks.

At a recent symposium on rubella infections held in Philadelphia,[2] a report of a prospective study after proven rubella infection indicated an over-all risk of congenital malformation for the first trimester to be about 19%. This study found in the first four weeks a risk of 47%; from five to eight weeks a risk of 22%; and from nine to 12 weeks a risk of 7%. Another preliminary report at this symposium suggested that gamma-globulin prophylaxis, after known exposure to rubella, may decrease the incidence of both clinical and subclinical rubella infections and, therefore, the incidence of malformations. Well controlled studies of this treatment are needed before it can be recommended. Such studies on the natural history of maternal and fetal rubella, on prophylaxis and the development of new tests for diagnosis will do much to remove the uncertainties about past and present infection and will clarify the prognosis for the infant. Since the most critical period for the fetus is in the early weeks of pregnancy before the mother seeks medical care, perhaps even before she knows that she is pregnant, the ultimate answer will be the development of an effective rubella vaccine which can be given to all children with booster doses for married women. Until these problems are solved the issue of the pregnancy complicated by rubella remains urgent.

Maternal rubella infections also cause an increased rate of spontaneous abortion. Physicians have long assumed that spontaneous abortion is the result of a natural-process selection. The evidence so far accumulated supports the assumption that spontaneous abortions are usually associated with gross congenital deformities, major deformities incompatible with life, or chromosomal aberrations. We infer, therefore, that spontaneous abortion is not a pathologic process, but an efficient, beneficial and necessary process by which defective fetuses are eliminated.

If spontaneous abortion is the natural process by which deformed fetuses are rejected, and if the observed increased incidence of spontaneous abortion after rubella infection is compatible with this hypothesis, then the process functions inadequately, for many deformed infants are not rejected *in utero*. Surgical intervention is frequently indicated when other body functions fail. Therapeutic abortion is often sought by pregnant

You've Made Us Change

APACHE MEDICAL COMPLEX

We started with plans for the most modern, most efficient, most tenant-oriented *medium-sized* medical complex in Minnesota. Your response forced us to change our plans. Now we're going to construct the most modern, most efficient, most tenant-oriented *large-sized* medical complex in Minnesota, to be built at Apache Plaza in two medium-sized stages. Stage 1, pictured above, will be ready for you in Fall, 1966.

Here are some of the reasons why Apache Medical Complex will be the ideal location for your new office:

women who have maternal rubella and do not have a spontaneous abortion. The surgeon who intervenes when other normal processes fail may on this basis find justification for therapeutic abortion, even though there is a good chance that the fetus may be normal. The analogy to the removal of a normal appendix after operation for suspected appendicitis is inadequate, though common enough to offer a parallel.

This suggestion that therapeutic abortion may be a remedy for a suspected malfunction of the normal process of spontaneous abortion is not offered as an excuse for the indiscriminate use of the curette. It is offered as a justification for such last resort treatment when careful consideration by both parents and physician has been given to the diagnosis of rubella, the stage of pregnancy, the likelihood of deformity and normality in the fetus, and the danger of the operation.

If the concept that a natural process of selection is active in determining the fate of a conceptus by balancing its metabolism and physiology in some yet unknown way to tell if it is normal or abnormal and then preserving the nidation* or initialing abortion, the natural law argument that pregnancy alone is normal is nullified. Then the ethical considerations for termination of pregnancy when fetal congenital malformations are suspected become personal matters to be decided by the parents and the physician.

If faced with this problem, the parents and the physician should consider carefully all the scientific facts available as well as the intangible doubts and dreads, and without hesitancy seek the counsel and advice, but not the dictate of minister, priest or other physicians. As yet, the legal justification for therapeutic abortion for suspected congenital malformation in a fetus does not exist in most states; but personal observations and historic precedent indicate that medical practice is usually in advance of both clerical and legal reform.

Letter to the Editor:

Pertaining to your Toonerville remarks, I am distressed to hear that you think that we who live in small towns do not practice up-to-date medicine. I can assure you that we do. — M.D.

Editor's note: See Soliloquy below.

The Editor's Soliloquy

Toonerville*

I quess I "goofed," was misunderstood, and I feel badly! I apologize! There are no longer any doctors in Toonerville. They all moved out. In Grandfather's day I was raised in a Toonerville, where the only evidence of modernity was a postoffice and a whistle stop on a branch line of the Milwaukee Railroad. There were endless prairies, sky and sunshine, with the closest neighbor miles away.

In my teenage mind — though our Toonerville was a single street with a dust-covered road leading to the swimming hole, and with more than enough territory for any man to roam, to fish in the creek, or to enjoy nature — I wondered why anyone would want to move to a larger metropolitan area, only to succumb to the 'rat race.'

In those horse-and-buggy days our doctor conducted a thriving practice from the hair-cushioned seat of his one-horse surrey. Many a time I rode with him on his daily rounds out into the Dakota hills, with the privilege of holding the reins while he compounded aromatic medicines, perused a magazine with strange and incomprehensible drawings, or occasionally took a snooze as he relied upon me to deliver him to the home of the next sick Indian.

By the time I had finished high school the doctor had moved from our Toonerville; and ever since then a half dozen local families here and there, abetted by the government, have tried to persuade doctors to move back to the Toonervilles all over the country. But only if our republic is taken over by a dictator or surrenders to a dynasty, will we physicians consent to practice medicine under such benighted or debased conditions.

The small towns in our nation, now with ready access to hospitals and medical facilities, are the most rewarding places to live. For gratifying interpersonal relationships they have no peers. They cherish rich traditions and foster cultural and intellectual pursuits on a par with those maintained in any large metropolitan center. These smaller towns are the heart of our society; they are the communities in which a physician can live a full life and serve humanity capably and devotedly, as he had originally planned to do when he took up the study of medicine.

Though some small towns do not have as many physicians as they could accommodate, it is not these small towns to which the government wants us to move. It wants us to move to the Toonervilles, the towns that cannot support a modern medical practice: the towns with a postoffice and a whistle stop and endless miles of nothing, where no doctor could practice good medicine even from a down-cushioned seat in his automobile.

Carl O. Rice, M.D.

Curbstone Consultation

Chronic Bronchitis

QUESTION: In treating patients with chronic bronchitis by bronchoscopic aspiration, at what intervals do you carry out aspirations?

ANSWER: The majority of patients need but a single bronchoscopy, granted they stop smoking. Generally speaking, if very little emphysema is present, the outlook is an excellent one. On the other hand, if the patient already has severe emphysema, his chances of getting into difficulty are far greater, and subsequent bronchoscopies may be needed when the patient runs into difficulties, particularly with exacerbations of respiratory infection. Thus it can be said that the duration of the good result from the treatment outlined varies inversely with the severity of the disease.

David H. Waterman, M.D. for
Drs. Waterman, Domm and Rogers,
Knoxville, Tennessee

Isoniazid and Para-Aminosalicylic Acid

QUESTION: Would you recommend the use of steroid therapy in conjunction with isoniazid and para-aminosalicylic acid in the management of a case of primary tuberculosis? The patient is a six-year-old child with enlarged bronchopulmonary lymph nodes which have resulted in segmental collapse of the right upper lobe. She has been under treatment with isoniazid and para-aminosalicylic acid for four months without roentgenographic evidence of clearing of the chest problems.

ANSWER: Drugs such as prednisone and triamcinolone combined with anti-tuberculous chemotherapy have been tried in such cases, but the evidence does not indicate that it is of substantial benefit. If a favorable response results, it is generally felt to occur in those cases in which steroids are utilized early in the course of the disease — within the first three months of the illness. Therefore, I would not advise the use of steroids in the case under question. Management of these difficult cases is best shared with a qualified medical-surgical chest team.

The desire to take medicine is perhaps the greatest feature which distinguishes man from animals. — William Osler

Monitor physiologic conditions of interest with Sanborn "*Standard Unit*" systems

Probably no two hospitals exist which have identical surgical procedures, identical physiologic information display requirements, or identical budgets for OR monitoring equipment.

Yet costly, custom-built monitoring systems are *not* necessary in most cases to do the job the surgical team wants done: building from an extremely wide range of available, standard, compatible instruments, Sanborn can and does provide complete, dependably trouble-free monitoring systems to meet the specific and different needs of hospitals and medical centers world-wide.

Systems can range from a simple combination of a few units for visual display only of the ECG, one temperature and two pressure measurements, for example — to very comprehensive installations which display and record 20 or more phenomena simultaneously, and provide complete intercommunications facilities and specialized measurement and analysis capabilities as well.

Frequently-used Sanborn units for *visual display* include oscilloscopes for waveform presentation of rapidly-changing events, illuminated numerical readouts which display up to four phenomena in three-digit values, and large scale meters for slowly changing events.

For *graphic recording,* heated stylus and optical oscillographs provide high resolution, permanent analog chart recordings of conditions. For *permanent storage* of data, with the ability to recreate the conditions again and again and over an expanded or compressed time interval, Sanborn magnetic tape recording systems provide extreme fidelity and precision at lower cost than many systems of comparable performance.

From such standard Sanborn units or "building blocks", the hospital has complete *freedom of choice* in system capabilities — coupled with the *economies* of regularly-manufactured products available from a single, experienced source. Tell us what you wish to monitor and any special conditions of use, and we will outline without obligation our system recommendation and cost estimate, to meet your monitoring requirements. Sanborn Division, Hewlett-Packard Company, Waltham, Mass. 02154.

HEWLETT
PACKARD hp SANBORN
DIVISION

In addition to OR monitoring systems, Sanborn's new "780" modular units give complete flexibility and "add on" capabilities for bedside and central station monitoring in the ICU, recovery room and emergency room. New "780" brochure available on request.

Fracture–Trauma Conference

Replantation of Limbs

Dr. Gerald Shaftan*

This morning we are presenting a conference on a subject that has fascinated surgeons since antiquity — the replantation of amputated limbs. Our guest is Dr. Ronald A. Malt from the Surgical Services of the Massachusetts General Hospital and the Shriners Burns Institute, Harvard Medical School. Dr. Malt, an Established Investigator of the American Heart Association, three years ago reattached the amputated arm of a young boy. This probably was the first successful replantation. The following are the case reports of our own replantations.

Case Reports

Case No. 1

On November 10, 1962, a 52-year-old printer caught his hand in a rotary printing press. The hand was pulled off at the carpal-radial junction and was spun around and crushed in the press before being removed. The patient and the hand were brought to the hospital immediately, and while the patient was being resuscitated, the hand was washed, placed in a penicillin solution and refrigerated. It was then perfused at operation 90 minutes later. The carpus was transfixed with Kirschner wires and the radial artery anastomosed, using 6-0 silk. A single vein was repaired on the dorsum of the hand and ulnar artery continuity was restored with a saphenous vein graft. By this time the radial artery anastomosis had thrombosed and was taken down and redone. Postoperatively, capillary filling was noted for a period of 24 hours; but the hand then became obviously nonviable and was amputated on the fifth postoperative day.

Case No. 2

On November 22, 1962, during a store robbery, a 31-year-old male clerk had his left hand transected through the carpus with a meat cleaver. He was brought to the hospital with a policeman's night stick as an upper arm tourniquet controlling the hemorrhage and the hand dangling from the wrist by a 2-cm. bridge of volar skin. A catheter was immediately inserted into the radial artery and the hand was perfused with low molecular weight dextran in saline to which heparin had been added. After clearing the distal arterial tree, the radial and ulnar arteries were repaired, the carpal bones were fixed with heavy Kirschner wires to the radius, and four venous anastomoses were made on the dorsal and lateral surfaces of the wrist. The order of repair was dictated, in this instance, by the desire to preserve the bridge of intact volar skin.

---

*Associate Professor of Surgery, State University of New York.

Continued

Low molecular weight dextran was continued on the first postoperative day, after which systemic heparinization was given for four more days. There was minimal postreplantation edema. Intraosseous venograms on the fifteenth postoperative day demonstrated at least two intact venous channels, and arteriography one week later showed good flow in the radial and ulnar arteries. Subsequently the median and ulnar nerves and flexor and extensor tendons were repaired, and an opposition bone blocking of the thumb-index metacarpals was done. This has produced a functional hand with good sensation to touch, temperature and pin prick, although two-point discrimination is limited to 20-30 mm. at the finger tips. He has the ability to hold a glass and other large objects and has sufficient facility to strike matches. He has returned to work.

Case No. 3

In July 1964, a 28-year-old man apparently slipped under a subway train, crush-amputating his right upper extremity. On admission to the emergency room the few shreds of tendon attaching the arm to the body were divided so that a separate team was able to begin the perfusion and cooling of the arm through a catheter in the brachial artery. Again, low molecular weight dextran and heparin were infused until the perfusate returning from the veins was clear. The arm was placed in a bucket of iced saline and brought to the operating room with the resuscitated patient. The brachial artery was anastomosed first, and immediate perfusion of the arm was permitted with free venous back-bleeding. This enabled us to identify two major veins which were repaired prior to the stabilization of the humerus with a Rush pin. Infusion of low molecular weight dextran was continued postoperatively and apparently caused a good deal of bleeding, for within five hours after completion of replantation, the patient was returned to the operating room for ligation of numerous small arterial and venous bleeders in the distal stump musculature. Edema and bleb formation increased rapidly up to the third postoperative day, then gradually subsided. Five months later the Rush pin was removed, the humerus shortened two inches and fixed with an A-O plate, permitting good skin coverage. At the present time the patient is awaiting nerve repair; however, the tag approximation of the nerves done at the initial procedure has enabled some regeneration of nerve fibers. The patient has sensation around the elbow and on the radial border of the forearm and is able to contract his biceps muscle.

Case No. 4

In August 1964, a 15-year-old boy had his hand severed at the wrist by a sabre during a fight. The amputation was between the distal and proximal row of carpal bones. The hand had been transported in ice and was perfused as in the two preceding patients. The carpus was first transfixed with Kirschner wires, the radial and ulnar arteries were then anastomosed, and four veins on the dorsal and ventral surface were also repaired. The result was encouraging and good nail bed perfusion continued for four days. On the fifth postoperative day blebs began to form and some cyanosis was noted in the nail beds. The patient had been continued on low molecular weight dextran, 1,000 ml. per day, and subcutaneous bleeding had occurred at the amputation site. Removal of the clots under the skin was accomplished in the operating room, which relieved the occlusion of venous return; nevertheless, loss of fingertip viability progressed. At the eleventh postoperative day there was still some hope of salvaging the remaining phalanges and hand, but the necrosis slowly advanced proximally, and the hand was amputated on the twenty-fifth day.

Dr. Ronald Malt*

The group of cases that you have seen and some others like them certainly prove that there is no longer any question about the feasibility of replantation or much doubt about the functional benefits that can be realized for some patients. The real unsolved question is how to select those patients who are going to have enough return of function to make replantation worthwhile both from a personal and from an economic point of view. As far as the technic goes, it is really very simple and can be put down in recipe form.

Immobilize the Bone

First, one obviously has to resuscitate the patient. I feel a little embarrassed even to mention this among surgeons, but sometimes there is the same emotional reaction in the profession to the possibility of a replantation that is seen so often in the nonmedical public. We may completely lose sight of ordinary surgical principles when faced with this very dramatic procedure. Second, and perhaps simultaneously, the amputated part should be cooled. This may be done by putting it in a pail of iced saline or lactated Ringer's solution. Next, flush the arterial system with lactated Ringer's until the perfusate comes back clear, and then clean a little bit of dirt out of the wound; however, at this stage don't make a significant attempt at debridement. In the restoration itself the bone should be attached first. Shortening or reshaping the contour of the bone will increase the stability and the technical facility of repairing structures and resecting questionably damaged areas.

---

*Instructor in Surgery, Harvard Medical School, and Assistant Surgeon, Massachusetts General Hospital.

Repair Veins First

We firmly believe that the veins should be repaired before the arteries: first, because of the necessity with preliminary arterial repair for replacement of massive unchanneled blood loss, and second, because occlusion of the veins after arterial continuity is established produces venous hypertension and additional muscular damage.

Debridement

The arterial anastomoses being completed, perfusion of the arm then gives good indication of what needs to be debrided. Debridement must be thorough. Almost every unsuccessful replantation that I have seen failed because the surgeon was reluctant to remove dead tissue. After debridement, nerve ends may be joined for later identification, or perhaps primary repair is indicated in sharp transections more distally in the arm. Finally, the soft tissues are closed and the skin repaired, using available local material, split thickness graft if suitable bed is available, or pedicle flaps if necessary.

We do not use any anticoagulant or low molecular weight dextran in the postoperative period, because it is our feeling that platelet thrombosis is what dooms the arterial and venous reconstruction, and this is not prevented by anticoagulants. Furthermore, on the basis once again of replantations that have failed, many were unsuccessful because bleeding in the postoperative period either jeopardized the patient's life or produced hematomas that subsequently became infected.

Evaluation of the Subject

The conscientious surgeon must weigh evidence on three additional questions before he makes a decision to replant a limb.

Will replantation endanger the patient's life? The immediate hazard is that occult bleeding, a ruptured organ, or a catastrophe such as cerebral herniation may kill the anesthetized patient during replantation. Acidosis from the release of accumulated metabolites immediately after circulation is restored and hypotension from sequestration of plasma within the limb later may also complicate surgical management in the postoperative period. This is especially true if the amputation is many hours old and if the problems are not foreseen in time to be corrected. In the postoperative

Continued

period hemolysis and myolysis are less well treated; they are better prevented by not replanting the badly crushed or autolyzed extremity and by providing for venous drainage before arterial inflow is returned.

Clostridial gangrene and other infections may be lethal at any time, particularly after the cessation of antibiotic therapy. Sporulating organisms may persist in tissue for years until the proper anaerobic conditions for their growth occur.

What are the chances for recovery of function? The standard for comparison is first, the prosthesis. If a good appliance is available and if the amputation is so located that chances of nerve regeneration are poor, for instance below the knee, replantation hardly seems warranted today. In the upper arm, where a better prosthesis can be fitted the longer the stump, a case can be made for replantation to achieve a little more length even if the distal parts are beyond repair.

The condition of the nerves is next considered. Nerves cleanly severed by a sharp instrument and amenable to primary union naturally make the surgeon optimistic. In a recent crushing injury in which a hand was completely devascularized distal to the metacarpal heads, repair of the arterial palmar arch and of the venous drainage were not difficult tasks, but the grossly intact nerves never became capable of transmitting sensation, and the hand was useless.

A sensate hand is, indeed, better than a metal hook. The question is whether functionless feeling is of enough benefit for one particular patient to subject him to the ordeal that follows replantation.

What will replantation mean to the patient? In the best possible situation it will mean that part of a dominant upper limb with minimal injury away from the level of transection will ultimately be restored in every important way to a responsible person. In the worst, it will mean that an extremity of limited utility will be preserved for someone already incapacitated in body or mind at the economic cost of many hospitalizations and at the social cost of psychic invalidism and narcotic addiction.

Nevertheless, only when the surgeon is satisfied by every means available that the patient would be better off with an attempt at replantation than with revision of the amputation, is he justified in restoring a lost limb. The decision to perform an elective operation in an emergency is always more taxing than defining a course of action when life is at stake.

Dr. Shaftan

Thank you, Dr. Malt. I can see that a number of questions have already been answered by your illuminating discussion, but there is some difference of opinion on some points. In our last three cases, clearing of the microcirculation with a mixture of low molecular weight dextran and heparin was utilized. You apparently don't make any attempt to do this immediately.

Dr. Malt

No, but we do perfuse subsequently. My guiding philosophy in most surgery is to keep it as simple as possible and in general I am against using two teams. I would rather wait until I am absolutely certain that things are going to be O.K. before I perfuse the limb. Shorey's[1] experimental studies in Chicago compared low molecular weight dextran, heparinized saline and other perfusates for their effectiveness in clearing microcirculation in an amputated part. They found that heparinized saline was more effective than low molecular weight dextran, although I must say that intellectually my sympathies are with low molecular weight dextran.

Dr. Horace Herbsman*

The same study did show that low molecular weight dextran perfusion produced the least limb edema. While we combined low molecular weight dextran and heparin, which may be the ideal perfusate, we got edema in the last two cases. We feel that the adequacy of the venous anastomoses is more important in preventing edema than lymphatic regrowth or the type of perfusate.

Dr. Shaftan

Turning to the problem of the order of repair, we have preferred to anastomose the arterial supply first, permitting earlier oxygenation of the extremity. Free bleeding from the veins has facilitated venous repair, especially in the small veins of the wrist and hand.

Dr. Malt

With cooling of the extremity there is no great hurry to restore circulation rapidly; moreover, it isn't exceedingly time-consuming to do venous and arterial repairs. I don't see that we should lose more blood than necessary.

Dr. Herbsman

Perhaps in the upper arm or leg, venous loss would be so great as to be prohibitive, but certainly in the more distal transections we lost relatively little blood and were able to find veins for repair that were impossible to locate before arterial flow was established.

Dr. Shaftan

Dr. Herbsman has mentioned that we feel that adequacy of venous return is a paramount factor in preventing edema. How many arterial and venous anastomoses do you think are necessary?

Dr. Malt

Don't you think that you ought to do as many as you can — within reason? In the upper arm one artery and one vein will do. In the hand one should try to repair the radial and ulnar arteries and two or three veins. We connected only one vein in the arm, and I know of at least two other replantations in which only one vein was connected without subsequent significant edema. We should try to do the tendon repairs at the primary operation. If everything else is *perfect* it would also be advantageous to repair the nerves.

Dr. Herbsman

We feel that repair of more than vessels and bone at the time of replantation adds unnecessarily to the procedure when the survival of the extremity is still not assured.

---

Continued

Dr. Joseph Tuby

If the limb is not brought with the patient, what is the time limit after which it should not be replanted? If you cool the limb while resuscitating the patient, does that change your time limit?

Dr. Malt

Several bits of experimental evidence bear on that, but clinical evidence suggests that you can get limb recovery up to six hours at room temperature. While definitive studies have not been done, Nabseth's[2] work suggests that you can probably get survival within 18 hours if a limb is cooled.

Dr. Herbsman

Lapchinsky[3] in Russia successfully autotransplanted canine limbs preserved for as long as 28 hours at 2°-4° C., with full return of muscle and nerve function.

Dr. Marvin Gliedman

How many tries have been successful?

Dr. Malt

I know of about 36 replantations; we have had two. By definition all replantations are of complete severances. Approximately 12 to 15 have results that I think would please the patient.

Dr. Shaftan

Thank you, Dr. Malt, for coming down to participate in this conference. I hope it stimulates prudence as well as interest in attempting replantation of amputated extremities.

Anglo Saxon Leech Craft

If the shanks be broken, take bonewort, pound it, pour the white of an egg out, mingle these together for the man whose shanks are broken. For a broken limb, lay this salve on the broken limb, and overlay with elm-rind, apply a splint; again, always renew these till the limb be healed. Clean some elm-rind, and boil it thoroughly, then remove the rind, take ground linseed and brew it up with the drink of elm. That shall be a good salve for a broken limb.

Malignancy of the Female Genitalia

The Status of Radical Surgery in the Treatment

The history of surgery as treatment for malignant lesions of the female genitalia is a long and familiar one. Since Wertheim[1] first described his surgical approach to cervical carcinoma there has been an emotional reaction to the mere mention of radical pelvic surgery among physicians. These reactions have resulted in periods of popularity for radical surgery alternating with periods during which radical surgery was almost dropped from the armamentarium. The present period might be called one of popularity for such surgery and dates from Meigs' first case in 1939, or more substantially from his first report in 1944.[2] This adoption and subsequent rejection of the use of radical pelvic surgery was implemented by the constant striving to improve the results of treatment. Radical surgery was displaced when radium became available, and this period was prolonged by the development of x-ray treatment.

World War II accelerated the return of radical surgery by virtue of stimulating the development of anesthesia, antibiotics and blood banks. This great interest in surgery over the last 25 years has, no doubt, acted as a stimulus to radiologists to improve their methods as well as their results. Supravoltage therapy has evolved during this period and has brought both improvement in results and new complications. Another development during this period has been improved communication throughout the world. At the same time standardized methods of reporting have been adopted, leading to the full realization that neither surgery nor radiation alone can achieve maximum benefit for patients with pelvic malignancy. Table 1 demonstrates the fact that the majority of cases of carcinoma of the cervix as of 1958 were still in advanced stages when detected. This means, as shown in Tables 2 and 3, that approximately one out of every two cases seen and treated will result in failure, not to mention the complications of treatment that will occur. If radiation fails in a case of early Stage II carcinoma of the cervix the only hope left for

Continued

that patient is radical surgery. In the most optimistic clinic in the world radiation will fail in one out of four cases of Stage II carcinoma of the cervix, while in practically all clinics of the world the failure rate in Stage II is approximately 50 per cent.[3] Thus we have entered a new period in the history of radical pelvic surgery, namely, one in which its place is secure and equal to that of radiation therapy. It seems fitting to spell out this status of radical surgery.

Ovarian and Endometrial Carcinoma

In such a discussion it is logical to consider the problem from the standpoint of primary cancer sites. Ovarian carcinoma can quickly be dismissed from the discussion as there is no place in the treatment of this disease for radical operations. Total abdominal hysterectomy with bilateral salpingo-oophorectomy constitutes the treatment of choice for malignant ovarian lesions. As the lymphatic drainage of the ovaries is primarily to the para-aortic nodes, lymphadenectomy is illogical. The typical intraperitoneal spread of ovarian carcinoma similarly makes radical removal of the pelvic organs useless.

In the case of endometrial carcinoma much the same conclusions have been reached, namely, that radical pelvic surgery is of no value, a not-so-obvious fact that had to be demonstrated by actual clinical trials.

Carcinoma of the Cervix

Cervical carcinoma spreads primarily to pelvic structures which can be encompassed by radical operations, a fact which has led to the development of the surgery under discussion, and it is the most common pelvic malignancy, making up 50 to 55 per cent of all gynecologic malignancies. It is the second most common malignancy in the female.

Contraindications for Radical Surgery

There is wide general agreement that radical pelvic surgery should not be employed as a palliative measure. If, at the time of surgery, spread to para-aortic lymph nodes or other upper abdominal structures is found, then the case should be considered nonresectable and closed.

It has been found that radical radiation and radical surgery, when combined for primary therapy, add significantly to the morbidity and mortality resulting from either alone but do not significantly raise the survival rates.

Radical surgery is, by definition, inadequate therapy for Stage III carcinoma of the cervix and doomed to fail, since the disease has already reached the lateral pelvic wall. In Stage IV carcinoma of the cervix radical surgery is generally contraindicated. There is an occasional case with anterior or posterior extension but little or no lateral spread. In such Stage IV cases radical surgery can be employed; however, there is little enthusiasm for its use anywhere in the world. Thus, the use of radical surgery in the treatment of cervical carcinoma is limited to Stages I and II, as well as to recurrent cases.

Radiation and Radical Hysterectomy

Stage I lesions of the cervix lend themselves well to either radiation or radical hysterectomy. The five-year survival rates as shown in Table 2 range from 70 to 90 per cent; however, the differences in survival rates are probably not as great as those figures suggest. In order to assess this more meaningfully it is important to know the proportion of microinvasive cases included in a given series. This was well illustrated by Latour,[4] who demonstrated a 95.4 per cent survival in microinvasive cases or Stage I A, as opposed to a 73.1 per cent five-year survival rate in Stage I B or clinically apparent Stage I cases. Thus it seems reasonable to equate the results achieved with radiation and radical hysterectomy in Stage I carcinoma, at least until more detailed analyses are available. Radical hysterectomy seems the more desirable method in cases of Stage I A because it is less apt to interfere with vaginal function; furthermore, such patients are usually quite young.

Brunschwig[5] reported an unselected group of cases of cervical carcinoma treated by radical surgery; Masterson[6] reported an unselected group of Stage I cases treated by radical hysterectomy. In both instances the purpose was to assess the role of radical surgery without selection of cases. Where serious medical problems are encountered which make the patient a poor operative risk, radiation therapy can be used with less danger to the patient.

The Risk of Fistula

Many will quickly point out that there is an increased risk in radical pelvic surgery from fistula formation; but it now seems possible to reduce this complication to a level comparable to that with radiation therapy.

Continued

Antoine, Louros, and Debiasi[7-9] have reported fistula rates of 1 to 2 per cent, in marked contrast to the usual figure of 8 to 10 per cent. As Masterson[6] pointed out, the high fistula rate after radical hysterectomy is usually found in clinics where physicians are being trained to do this type of surgery. It should also be pointed out that the control of radiation therapy has been less rigorous in the past than has control of operative procedures. In many cases follow-up after radiation therapy has been poor and radiologists' knowledge of their own results somewhat sketchy. In contrast to this, radical pelvic surgery has been almost entirely limited to centers or to private hospitals with surgeons operating as consultants from centers. Briefly then, it seems reasonable to equate the over-all results of radiation and surgery in the treatment of early carcinoma of the cervix. The results of these two modalities when compared in the treatment of late carcinoma of the cervix might also be equated in terms of 5-year survival rates. A comparison, however, in complications rates would demonstrate an unequivocal superiority of radiation therapy.

Recurrence

As noted previously some 10 to 30 per cent of Stage I cases of carcinoma of the cervix and approximately 40 to 50 per cent of Stage II cases treated by radiation therapy will prove to be persistent or recurrent, a fact that led to the development of more radical surgical procedures. In large clinics today with active and well organized follow-up procedures all cases of cervical carcinoma are carefully followed for evidence of persistent disease or early recurrence. This is most important during the first two years following treatment, when recurrence is most apt to occur. If one can detect recurrence of a Stage I or II carcinoma of the cervix in its early phases, it may be possible to eliminate the disease by a radical hysterectomy. This concept is important because the problem involves a great many patients, and very young patients for the most part. If recurrence is detected in later phases, then it may be necessary to carry out an exenteration* to encompass the lesion.

Modalities of Therapy

Whether one does an anterior, a posterior, or a total exenteration depends, of course, on the location and extent of the lesion. Brunschwig[10] has indicated a 20 per cent salvage of patients undergoing exenterations, and TeLinde has found anterior and posterior exenterations to have a definite place in the over-all management of these problems, although he has used the total exenteration less and less with time.

Anterior Exenteration

The anterior exenteration is a formidable procedure and one that should be undertaken only by surgeons experienced not only with the technical aspects of the operation but also with the difficult problems associated with urinary diversion. At the present time the ileal conduit is the method of choice for urinary diversion. If done properly this type of diversion eliminates the problem of electrolyte imbalance associated with ureterosigmoid anastomoses. The ileal conduit also carries with it a lower incidence of pyelonephritis but is still subject to stenosis and obstruction of the ureters at the site of anastomosis with the ileal segment.[11]

Stockholm	2056	54.5
Manchester	1760	42.1
Houston	789	63.2
N. Y. Presb.	343	48.4

Posterior Exenteration

The posterior exenteration is the least formidable of these ultraradical operations. It differs from the well accepted abdominal perineal resection mainly in that a radical hysterectomy is part of the procedure.

Certainly one should not undertake the management of malignant disease unless he is capable of offering the patient all possible modalities of therapy. Similarly, one should not undertake methods of therapy he is not qualified to administer or the complications of which he is incapable of managing. On the other hand, a physician should not deprive a patient of a type of therapy which may be of benefit simply because he is not trained to do it himself. We should not condemn methods of treatment without a fair assessment of them. The complications of exenterations are significant in both frequency and seriousness; however, it must be emphasized that these procedures are being used, for the most part, when all else has failed.

Radical Vulvectomy

Malignant lesions of the vulva constitute approximately 5 per cent of malignant lesions of the female pelvic organs. The vast majority of these cases are squamous-cell carcinoma. The treatment of this disease at present is primarily surgical and takes the form of radical vulvectomy with regional node dissection. Radiologists are not at all enthusiastic about the use of radiation therapy in the treatment of vulvar carcinoma, and its use is limited almost entirely to palliation for either far advanced cases or recurrent cases after surgery. The survival rates in Stage I carcinoma of the vulva (Table 4) are in the general range of 80 per cent. This survival rate drops precipitously in the case of Stage II carcinoma of the vulva where regional node metastases have occurred. The further decline of survival rates is seen in Stage III carcinoma of the vulva with direct extension to the anus, urethra or vagina. If these survival rates are to be

TABLE 4
Survival in Cases of Vulvar Carcinoma by Stages

	Stage I* % 5-Year Survival	Stage II % Survival	Stage III % Survival
Taussig (1917-1935)	63.6	52.6	
Way (1949-1954)	77	42	
Green (1927-1950)	86	47	9.7

*Staging explained in the text

Continued

improved, I believe more information will have to be obtained concerning lymphatic spread beyond the pelvis in those cases with positive regional nodes. Furthermore, those patients with direct extension to the urethra, anus and vagina will require more radical surgical procedures to eliminate the disease locally. The natural tendency in such cases where the urethra is involved, for example, is to transect the urethra just proximal to the gross disease in order to preserve the bladder function. The results from Green's Report as shown in Table 4 clearly demonstrate the seriousness of involvement of these structures and warrant a trial of more radical procedures rather than less radical ones.

Conclusions

Radical pelvic surgery has secured a place in the management of early carcinoma of the cervix and in recurrent carcinoma of the cervix. It is also the basic method of treatment of carcinoma of the vulva.

Neuro-Pediatrics Conference

School Failure*

Normal Intelligence — Neurologic Disease

This 8½-year-old white female was referred by Dr. C. F. Reichelderfer of Staples, Minnesota, to the University for evaluation of learning disability. Information received from Miss Charlotte Kummert, Principal of Staples Elementary School, Northside, indicated that the child has had difficulty following instructions and remembering what she has recently learned. In addition, she has great difficulty in reproducing numbers, figures and symbols.

Dr. Marcia Hyvarinen:**

This child's delivery was uneventful following an apparently normal pregnancy. Birth weight was five pounds, six ounces. Growth and development were unremarkable (aside from difficulties with her left thumb) up to the time of school participation. Because of problems in learning, she has repeated the first grade twice and now is failing a third time. Revised Stanford-Binet, administered by Dr. Ruth Hill in Staples, yielded an I.Q. of 109 on May 25, 1964. It was Dr. Hill's conclusion at that time that although the child was of high average intelligence, she demonstrated marked deficiencies consistent with cerebral dysfunction. On the basis of Dr. Hill's conclusions, special instructions were arranged in the Staples School System, which included several hours per day of home-bound instruction and one-half day in regular first grade class. The response to date from this approach has been minimal.

No clear definition was obtained as to the duration of motor difficulties noted with the left thumb. Information obtained from the mother by several different investigators suggests that the weakness may have been present since early infancy; to others the mother related that it has been

---

*Held on Wednesday, March 17, 1965 at 1 p.m.

Sponsored by the U. S. Public Health Service Grant N2502A63. These conferences are an integral part of the Comprehensive Clinic Program at the University of Minnesota Hospitals. The pediatric conferences are held weekly from 1 to 2 p.m. every Wednesday. The adult conferences are held every Thursday at 4 p.m. Co-ordinators for the project are Dr. Edward C. Defoe and Dr. Charles Branthaver in Pediatrics and Dr. Robert Soll, in Adult Neurology.

**Senior Medical Student, University of Minnesota Hospitals.

Continued

present for only the last three years. The child was pulled from a couch at the age of six weeks by her older sibling; however, there is no recollection of any specific injury at that time. Whooping cough, chicken pox at eight to ten months, mumps at four years, and measles at five years were said to be mild and without after-effects. Family history revealed that the father died following an accident approximately eight and one-half months prior to the child's delivery. One older male sibling also repeated the first grade but is reported to be doing A and B work currently in school. The mother is apparently well.

The physical examination revealed a small, pleasant, dark-eyed, shy and cooperative girl. Weight and height were about the 16th percentile. Aside from neurological findings and the problems of writing and symbol recognition, nothing remarkable was found. Electroencephalograms and skull, cervical and thoracic spine X rays were within normal limits. Bone age as interpreted from wrist films was one and one-half standard deviations below the mean for chronological age.

Electromyogram showed evidence of chronic denervation in the left thenar muscles. There was also denervation in the left first dorsal interosseus, which is innervated by the ulnar nerve. The evidence for chronic denervation in the left thenar muscles was interpreted as indicative of carpal tunnel syndrome, etiology unknown. There was no explanation given as to why the ulnar innervated muscles were also affected.

Dr. Mark Nesbit:* The possibility of metabolic defect with amino aciduria was thoroughly explored in this child. However, all the tests were negative.

Dr. Paul Moe:** The history here was interesting but confusing. The birth weight of five pounds, six ounces in a child said to be full-term and possibly overdue, may be indicative of an intra-uterine problem with secondary contribution to cerebral dysfunction. Other possibly pertinent points in the history are: (1) regurgitation noted in early infancy; (2) pertussis at near the end of the first year; (3) the mother's observation that the child has always been right-handed. Regurgitation may have been a reflection of intracranial pathology. Although the pertussis was described as mild, the disease occurring in infancy must always be suspect as a contributor to pathology in a child manifesting central nervous system disease

Dominant Handedness as an Infant

Confusing was the discrepancy in the story concerning left-hand disability. As dominant handedness is not present in a child under one year, the observation of right-handedness from infancy suggests an early problem with the left arm. If this was present at birth, or following trauma at a later date, with brachial plexis stretch, it appears likely it would have been recognized and clearly related to at the time.

On physical examination, I found her left hand to be smaller than the right with the forearm 1 cm. less in circumference than the right. Tendon reflexes in the left arm were less than on the right, and left-hand strength was significantly decreased. Difficulties in grip and palmer adduction of the thumb were consistent with ulnar nerve disability. Mild dorsiflexion weakness of the wrist and opponens paresis were consistent with radial and median nerve involvement. Triceps weakness suggested C7-8 involvement. Slight pronation posturing of the left hand was also apparent. Tests for parietal lobe function, such as evaluation of textures, recognition of finger writing, et al., were not performed as well on the left as on the right. Touch and pain sensation were normal bilaterally. Cognitive* tests, such as knowledge of age, time, day, month, and year were also performed less well than one would expect for a child of this age. These observations, plus the small hand size, are consistent with a right parietal lobe lesion. Parietal lobe disease presenting prior to two years of age may produce a decrease in extremity size; after that time this is not likely to be true. However, in addition, fasciculations of the left thenar eminence and palm were noted. These are pathognomonic of a lower motor neuron lesion. So we must consider two lesions here: one in the right parietal lobe and the other most likely in the spinal roots of C7-8. As the electroencephalogram is positive in 80% in some series of children with parietal lobe involvement and reading problems, a negative electroencephalogram here is a bit unusual. The electromyogram interpretation of slowing of median nerve conduction of the wrist as being indicative of carpal tunnel syndrome is based upon very limited muscle evaluation and should be repeated. The results noted here could just as well be derived from a lesion high in the brachial plexis or cord at C7-8.

---

*Pediatrician, University of Minnesota Hospitals.

**Pediatric Neurologist, University of Minnesota Hospitals.

Dr. Edward Defoe:** Is this problem with the left arm one you might expect as the end result of a Klumpke† type brachial plexis stretch?

Dr. Moe: Yes. However, that seems unlikely as there is no history of such a traumatic episode.

Dr. Defoe: What are your recommendations?

Dr. Moe: I would suggest a repeat electromyogram for more thorough muscle evaluation, and a myelogram to rule out the possibility of a neoplastic process in the area of C7-8. Myelography is a relatively benign procedure. The chances of arachnoiditis developing as a complication are minimal, if the dye is carefully removed. As to the alternatives, we can watch and see if the condition is a stable one. If we could determine that the arm problem had been present since infancy, this alternative would most certainly be the proper one.

Dr. Frank Lassman:‡

This child's reading ability was evaluated, using standard testing instruments. She was found to read at approximately the second month of the first-grade level. She is presently in the first grade for the third time. Arithmetic was evaluated similarly, and her ability to handle problems presented visually was even less than the reading ability described above. On the other hand, she was slightly improved when the problem was offered auditorily. The child's language aptitude was assessed in a screening fashion, provided by a vocabulary test. I was surprised to find a reduced vocabulary score of six years and four months (Nashville norms). The modified interpetation of this performance suggested a vocabulary level of no better than six years.

Visual Discrimination

The fact that this test required a visual stimulus as well as an auditory one should be kept in mind. Here the child is offered a word and is asked to choose from among the four pictures on the page. A primary visual discrimination deficit might influence her performance. Visual discrimination was measured using both formal (Frostig) and informal procedures. As long as the task did not involve her own motor performance, the youngster was able to score up to age. Visual motor performance fell rather significantly below the visual discrimination ability. The child was able to do quite well with visual motor performance until the task became very complex. The ability to copy directly was slightly better than copying from memory. Memory did not appear, however, to be the primary factor, but rather to introduce an additional step. The copying of the diamond figure as described in Dr. Hill's report was failed. Visual memory test was passed as long as this area was uncontaminated by the diamond-copying problem. She was entirely unable to identify letters with any precision. She failed approximately two thirds of the task requiring that she identify capital letters and small letters out of context. With regard to phonics, she was unable to associate the sound of the letter with the appropriate printed letter, or to make the sound when the letter was pointed to.

Tactile Agnosia

She demonstrated tactile agnosia.* Errors were observed when the left hand was compared with the right. On the basis of evidence elsewhere, it would be difficult to assume that this was secondary to central factors, since some peripheral damage is apparently present. She was unable to recite the alphabet, the days of the week, or the months of the year. This finding should be considered in association with the reduced vocabulary score above.

My impression was that this youngster, apparently of normal intelligence, has reduced ability in learning to read, spell and do simple arithmetic. She has a severe deficit in letter identification, tactile agnosia, and reduced verbal ability represented by reduced vocabulary and alphabet series. I would recommend that remedial reading should be continued with work at a primitive elemental level. In addition, vocabulary building should be instituted.

Dr. Moe: Does she fit the category for specific reading difficulty (dyslexia) ?

Dr. Lassman: Yes. However, this is a very broadly defined entity.

Mrs. Mary Cordingley:** The mother was interviewed to gain a picture of the present home situation and to learn about relationships with family members. The mother is a quiet woman, unable to talk freely about her situation. She reveals great tension through tremor and chain smoking. She quit school at the ninth-grade level, married at 17 and had three unhappy married years, as her husband traveled from relative to relative looking for a job. She has been widowed now for eight and one-half years and receives financial benefits from social security and several other sources. Although the amount is adequate for ordinary maintenance, she is unable to manage financially and is deeply in debt. She also has been unsuccessful in her attempts at work to supplement the income. She spends her days "bumming around" town and her evenings with her closest friends who own and work at a bar. She said she didn't mind her life; but with questioning she told of making two attempts at obtaining further education. On one occasion she spent $200 for a correspondence course and also tried an illustrator's course; but she has been unable to complete either one. She has little contact with her children; consequently they have had little opportunity for adult identification. She has, however, done a little art work with them. She feels the in-laws prefer the boy and ignore the patient. No doubt the financial situation has influenced her life. The family income will diminish in two years and end in ten to eleven years.

---

*See Test Your Word Score Page 1639.

**Social Worker, University of Minnesota Hospitals.

There is great need for realistic planning for this disturbed, somewhat withdrawn woman. Supervision of the financial area should be considered. Association with an appropriate mental-health center might be arranged through the Todd County Welfare Department. The in-laws should also be considered in the planning.

Dr. Harold Ireton:* The patient was tested at the chonological age of eight years, seven months. Intelligence testing (Wechsler Intelligence Scale for Children) indicated dull-normal verbal ability (I.Q. 86) and average performance ability (I.Q. 99). Among the verbal tests most adequately performed were tests of practical judgment and abstract ability. She did relatively poorly on sub-tests measuring fund of information or arithmetic ability and vocabulary. She demonstrated average ability on all performance tests except the picture arrangement sub-test, wherein pictures must be arranged in logical sequence to tell a story. In this test, on one occasion, she arranged the story from right to left, which may be analogous to her reading reversal. Her Goodenough production was significantly below average for her age (M.A., 6.6-I.Q., 78). On the Bender-Visual Motor Gestalt she showed as striking an inability to reproduce acute angles as in attempting to copy diamond-shaped figures. Such inability at her age is strongly suggestive of some organic defect. On the basis of these results I agree that her school difficulties are not based on general intellectual deficit but rather on some more specific learning disability which is probably associated in large part with organic involvement.

The mother herself presented as a rather vague person who is little concerned about her appearance. Brief intelligence testing indicated average ability (I.Q., 105). Her Minnesota Multiphasic Personality Inventory profile, which is apparently valid, suggested considerable psychological disturbance, probably of major proportions. She acknowledges symptoms of depression, anxiety, paranoid thinking, personality disorganization and social isolation. It may be that she maintains a chronic marginal adjustment in a relatively nondemanding environment.

Dr. Defoe: Would you care to comment upon the relative effect of primary cerebral disability versus environmental factors in the initiation and perpetuation of this child's learning disability?

Dr. Ireton: Yes, both appear to be important. How to quantitate the relative importance of each is always a problem for which we have only poor answers.

Dr. Defoe: I note that the child spends one-half day in special tutorial sessions with a home-bound instructor. In view of her limited exposure to

---

Continued

contemporaries, would this not better be performed in an environment with other children where she would receive greater opportunity for socialization?

Dr. Ireton: Yes, this is important. She should have as many reassuring social experiences as possible.

Dr. Charles Branthaver:* What is the interplay between parent and child here? To be maximally effective, remedial reading activity usually needs support from home.

Dr. Ireton: The mother is somewhat empathic regarding this problem; however, I doubt if there is much meaningful support given.

Dr. Nesbit: Perhaps the grandparents should be brought more actively into a supportive role.

Dr. Defoe:

There are three major problem areas here:

Accurate Determination of the Difficulty

A repeat electromyogram should help us to more accurately determine the extent of muscle involvement. A myelogram should be done to rule out a progressive cervical cord lesion, unless with further investigation within the community, family and other appropriate sources, we can determine that this problem has been present since infancy. Without this, the possibility of a neoplastic process in the area of C7-8 cannot be logically ruled out.

Learning Problems

Remedial reading should be continued with work at a primitive elemental level. In addition, vocabulary building should be instituted (with continuing auditory reinforcement). However, as social factors may be decisive in the success or failure of such a program, environmental modification is indicated. Maximum socialization with her contemporaries within the school environment is essential. Means of moving her along in school with her social peers without increasing learning frustration should be explored. In addition, efforts should be expended to assess the home environment and the manner in which this can be made maximally supportive with a minimum of frustrations. This assessment perhaps can be arranged through the Todd County Welfare Department.

Help for the Mother

The Todd County Welfare Board should be contacted with regard to arrangements for follow-up and evaluation care at a local mental health center. In addition, perhaps some vocational training aid can be given for development of greater economic self-sufficiency.

It seems wise that responsibility for continued medical evaluation rest at the University of Minnesota until the problem with the left arm has been more clearly defined. Staples School personnel and the Todd County Welfare Department will be directly contacted by Dr. Hyvarinen and Dr. Defoe. Interpretation of the conference to the mother will rest in their hands also, with Dr. Ireton's assistance. Following this definition, responsibility for ongoing medical care and coordination with school and welfare department should reside with Dr. Reichelderfer in Staples.

Acknowledgments

The moderator wishes to acknowledge the help received from Dr. Reichelderfer, the referring physician; Mr. Richard Hegre, Director of Elementary Education for the Staples School System; Miss Charlotte Kummert, Principal, and Mrs. Baker, Teacher, Staples Elementary Northside School; Dr. Ruth K. Hill, Psychologist, Staples School System; Mrs. Julia Zehnle, Caseworker, Todd County Welfare Department, in transmitting the necessary preliminary information for this conference. Unfortunately their active presence at the conference was barriered by the blizzard of March 17, 1965.

Drs. Werner Lund, J. E. Nord and P. J. Parker of Staples were also helpful in supplying data from their files.

DEJERINE-KLUMPKE SYNDROME

This syndrome consists of paralysis and atrophy of the small muscles of the hand and forearm with an associated Horner's oculopupillary manifestation. It is the result of involvement of the lower roots of the brachial plexus and affects particularly the nerves derived from the 8th cervical and 1st thoracic roots. The interossei, thenar, hypothenar, flexor carpi ulnaris and flexor digitorum muscles are involved, associated with a lack of sensation or, on some occasions, excessive sensibility on the inner side of the forearm. Pain may be a prominent manifestation. If the sympathetic rami are involved the Horner's syndrome is present with myosis, narrowing of the palpebral fissure and recession of the eyeball.

Birth trauma with hemorrhage as a localizing lesion may be an etiologic factor or there may be a fracture or dislocation of the shoulder. Correction of the causative factor may improve the prognosis.

Durham, Robert H. — Encyclopedia of Medical Syndromes,
Hoeber Medical Division, Harper and Row, New York

No physicking. We are a machine made to live; we are organized for that purpose, and such is our nature; do not counteract the living principle — let it alone — leave it the liberty of self defence — it will do better than your drugs. Our body is a watch intended to go for a long time. The watchmaker cannot open it, and must work at random. For once that he relieves or assists it by his crooked instruments, he injures it ten times, and at last destroys it.

— Napoleon Bonaparte to his physician, Dr. Antommarchi, 1820.

The essence of style, as I see it, is the avoidance of (1) wind, (2) obscurity.

— Walter Bett, M.D., Address to the American Medical Writer's Association

Butazolidin® alka

Each capsule contains:

Butazolidin, brand of phenylbutazone	100 mg.
dried aluminum, hydroxide gel	100 mg.
magnesium trisilicate	150 mg.
homatropine methylbromide	1.25 mg.

in painful shoulder

Geigy

Therapeutic Effects
The acute phase of subdeltoid bursitis, tendinitis and associated periarticular inflammation usually responds promptly and dramatically to phenylbutazone. Pain and tenderness may be relieved within 24-48 hours and mobility of the affected arm quickly restored. Full recovery is frequently achieved within 7-10 days so that therapy is generally of short duration. Calcific deposits are not specifically affected by treatment, but their presence does not appear to retard symptomatic improvement.

Phenylbutazone has not replaced physiotherapy, x-ray treatment, or local injections of hydrocortisone in the more chronic conditions, but it may advantageously be combined with these measures.

Contraindications
Edema, danger of cardiac decompensation; history or symptoms of peptic ulcer; renal, hepatic or cardiac damage; history of drug allergy; history of blood dyscrasia. Because of the increased possibility of toxic reactions, the drug should not be given when the patient is senile, or when other potent chemotherapeutic agents are given concurrently. Large doses of Butazolidin alka are contraindicated in patients with glaucoma.

Precautions
Before prescribing, the physician should obtain a detailed history and perform a complete physical and laboratory examination, including a blood count. The patient should be kept under close supervision and should be warned to report immediately fever, sore throat, or mouth lesions (symptoms of blood dyscrasia); sudden weight gain (water retention); skin reactions; black or tarry stools. Regular blood counts should be made. The drug should be used with greater care in the elderly.

Warning
If coumarin-type anticoagulants are given simultaneously, the physician should watch for excessive increase in prothrombin time. Pyrazole compounds may potentiate the pharmacologic action of sulfonylurea and sulfonamide-type agents and insulin. Patients receiving such concomitant therapy should be carefully observed for this effect.

Adverse Reactions
The most common adverse reactions are nausea, edema and drug rash. The drug may reactivate a latent peptic ulcer. Infrequently, agranulocytosis, generalized allergic reaction, stomatitis, salivary gland enlargement, vertigo and languor may occur. Leukemia and leukemoid reactions have been reported but cannot definitely be attributed to the drug. Thrombocytopenic purpura and aplastic anemia are also possible side effects. Confusional states, agitation, headache, blurred vision, optic neuritis and transient hearing loss have been reported, as have hepatitis, jaundice, and several cases of anuria and hematuria. With long-term use, reversible thyroid hyperplasia may occur infrequently.

Average Dosage
Initially, give 400 mg. daily (one capsule q.i.d), reducing this, if possible, when a favorable therapeutic effect has been obtained. If after one week there has been no response, discontinue the drug. Butazolidin alka contains antacids and an antispasmodic to minimize gastric upset.

Note: The physician should be fully aware of dosage, precautions, adverse reactions, and contraindications as contained in the complete prescribing information.

Athletic Injuries

Injuries of the Shoulder in Athletics*

Shoulder injuries occur rather frequently in contact sports, but rehabilitation is usually not so prolonged as it is in trauma to the weight-bearing joints. Essentially, there are four injuries involving the shoulder region which concern the team physician because of their frequency of occurrence. These include sternoclavicular separation, anterior dislocation of the head of the humerus, separation or dislocation of the acromioclavicular joint, and fracture of the clavicle. Three of these problems involve only soft tissue structures; if treated properly, the athlete usually may be expected to return to competition within three to six weeks from the date of occurrence. The fourth of these, the fractured clavicle, can, in most instances, be treated by closed method, with firm union expected in eight to ten weeks post fracture.

Diagnosis

Adequate initial evaluation of a shoulder injury requires that the athlete be undressed to the waist and that the examining physician keep in mind the possible diagnoses. Momentary subluxation or dislocation with spontaneous reduction before medical examination does not mean that the treatment should be any less energetic. Visual examination for asymmetri-

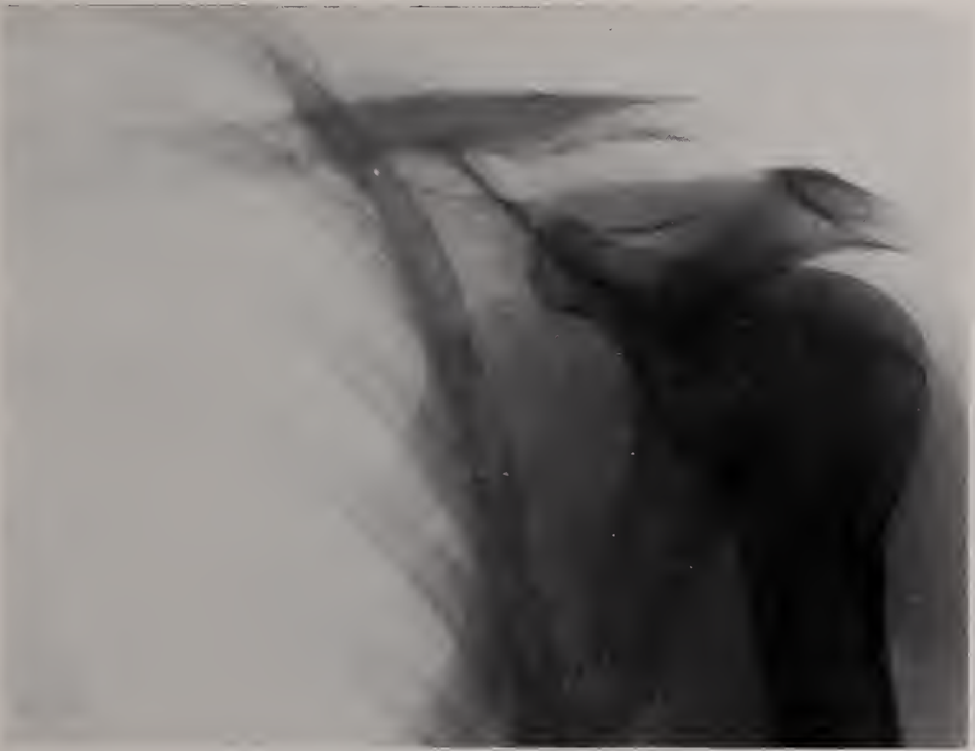

Fig. 1 — Separation of acromioclavicular joint.

---

*See Minnesota Med 48:1505 for third in this series. Sponsored by Minnesota Committee on Trauma of the American College of Surgeons.

cal contours is the first step. Evidence of ecchymosis, abrasion, or hematoma helps one to focus on the specific site of damage.

Palpation adds to our knowledge of the situation; tenderness and/or crepitus are, of course, significant findings to be sought. X-rays in at least two projections are mandatory.

Treatment

If one is quite sure that there has been a subluxation or dislocation of either the sternoclavicular joint or the glenohumeral joint with spontaneous reduction, treatment in a sling and swath for three weeks is indicated. If the injury to either of these two joints requires manipulation to accomplish reduction, then three weeks of continuous sling and swath are necessary if we hope to avoid recurrent, chronic subluxation and/or dislocation. A normal sternoclavicular or glenohumeral joint can be anticipated if this rather simple treatment is insisted upon. If the reduction by the physician is necessary, it is usually best to give heavy sedation and analgesia or general anesthesia for relaxation so as to avoid further injury to soft tissue structures and hyaline cartilage. Straight traction on the arm usually accomplishes reduction of either of these two injuries if relaxation is complete. Post-reduction X-rays should be taken to prove one's clinical impression of reduction.

Treatment of acromioclavicular joint injury is more difficult and there is less agreement on how these injuries should be handled. Acromioclavicular *separation* (Figure 1) occurs when only the acromioclavicular ligament has been ruptured. Frank *dislocation* (Figure 2) occurs when the cora-

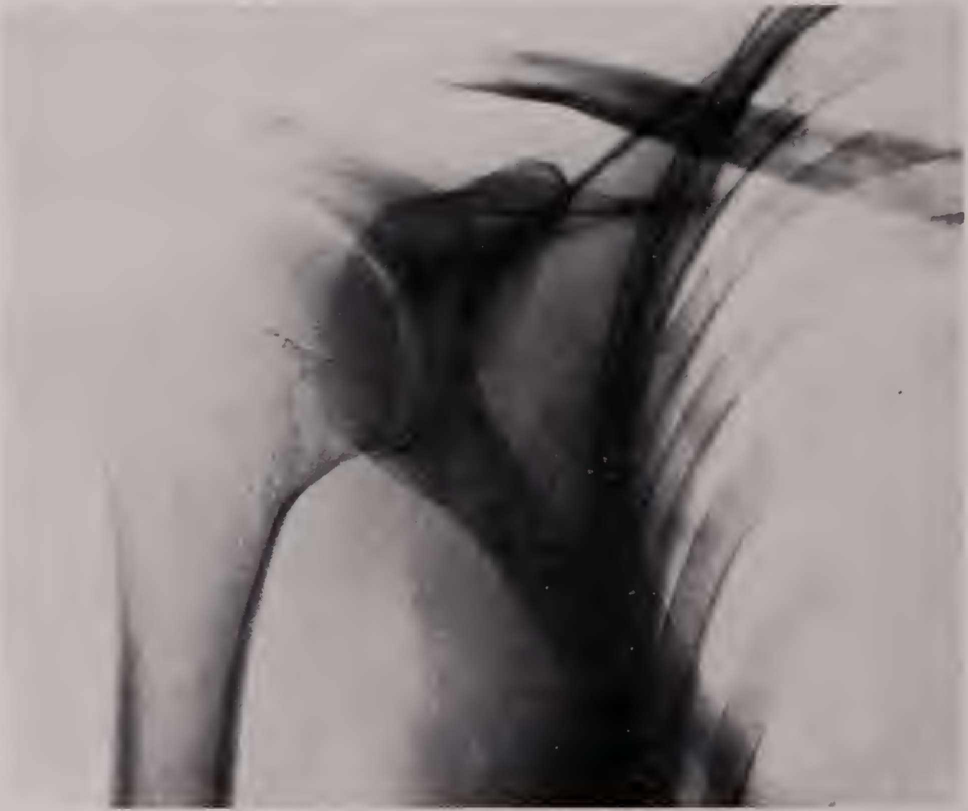

Fig. 2 — Complete dislocation of acromioclavicular joint.

coclavicular ligament, as well as the acromioclavicular ligament, has been torn. Some surgeons believe open reduction and internal fixation is warranted in both separation and dislocation in an athelete. Others feel that with mere separation, the individual is generally asymptomatic within 10 to 14 days, and that for those few who do have persistent complaints, late resection of the outer inch of the clavicle gives satisfactory function and strength. Most agree that complete dislocation in an athlete demands open reduction and some type of internal fixation for six weeks. Late onset of osteoarthritic changes at the acromioclavicular joint in those that are opened is high,[1] but resection of the outer inch of the clavicle can always be done for that eventuality. Patients with unrepaired acromioclavicular dislocations not only have a rather ugly deformity, but also often lose strength in the shoulder, especially when working with the arm above the horizontal.

Fracture of the clavicle can be treated by manipulation and application of a plaster figure-eight yoke to hold the shoulders in military position. Figure-eight straps or webbing are generally unsatisfactory, because of slipping and stretching of the straps, resulting in loss of position of the apparatus and alignment of the fracture. Caution must be exercised that the edge of the plaster does not cause pressure on the neurovascular structures in the axilla. Local instillation of two per cent procaine into the fracture hematoma affords rapid, simple, and safe analgesia for the manipulation and cast application.

Petrus Hispanus

In his Commentaries Petrus Hispanus (c. 1215-1277), self-styled "professor of the art of medicine and investigator of the truth," revealed his empirical bent by posing such provocative questions as:

Can natural death be retarded?

How can animals who eat poisons be food for men?

Why is man less hairy and of weaker constitution than the brutes?

Why are animals soft in infancy and fruits hard?

Should paralytics eat fried fish?

Why is oil best at the top, honey at the bottom, wine in the middle of the cask?

What part of water is more truly water: top, bottom, or middle?

Why are pigs' intestines the best of animals that walk and geese's intestines of those that fly?

Is human milk subtler than asses' milk?

If the spleen causes laughter by purifying the blood, why isn't love caused by the gall-bladder?

Is raw cheese better than cooked, and solid cheese or cheese with holes in it?

Why are fools so fond of cheese?

Why does human urine enrich vines?

Are apples good in fevers?

Why pepper is good for dimmed eyes?

Miltown®

An eminent role in medical practice

- Clinicians throughout the world consider meprobamate a therapeutic standard in the management of anxiety and tension.
- The high safety-efficacy ratio of 'Miltown' has been demonstrated by more than a decade of clinical use.

Miltown®
(meprobamate)

Indications: 'Miltown' (meprobamate) is effective in relief of anxiety and tension states. Also as adjunctive therapy when anxiety may be a causative or otherwise disturbing factor. Although not a hypnotic, 'Miltown' fosters normal sleep through both its antianxiety and muscle-relaxant properties.

Contraindications: Previous allergic or idiosyncratic reactions to meprobamate or meprobamate-containing drugs.

Precautions: Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of preexisting symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Usual adult dosage: One or two 400 mg. tablets three times daily. Doses above 2400 mg. daily are not recommended.

Supplied: In two strengths: 400 mg. scored tablets and 200 mg. coated tablets.

Before prescribing, consult package circular.

Child Psychiatry

Program of the Minnesota Residential Treatment Center

The Minnesota Residential Treatment Center serves emotionally disturbed children in need of intensive psychiatric treatment in a residential setting. The Center, established by act of Legislature in 1957, is administratively in the Department of Welfare. It is located at Lino Lakes, north of the Twin Cities on 160 acres of land contiguous to the Minnesota Reception-Diagnostic Center, a receiving center for children who are placed under the direction of the Department of Corrections. Both institutions are separately directed. Administrative services for both institutions, such as budgeting, inventories, payroll, personnel records, housekeeping, maintenance, and stenographic pool, are the responsibility of an administrator whose staff constitutes a unit of the Department of Administration. The first patients at the Treatment Center were admitted in June 1963. Its total bed capacity is 64 beds.

Intensive in-patient treatment is one part of a continuum of facilities for children throughout the State coordinated by the Director of Children's Mental Health Services for the State. His office integrates the medical services the State can offer to children, particularly services of institutional care and treatment. From his office come the referrals the director of the Treatment Center considers for admission. The chief criterion for referral is the likelihood that a child could benefit from intensive in-patient psychiatric treatment. Other functions of the Treatment Center are likewise related to the needs of the State.

The organization of the staff is designed to serve the multiple functions of the center and to treat a group of children which includes both sexes and a wide range of age, intelligence, and diagnoses. The age range is from six to eighteen; the I.Q.s of the patients may vary from borderline defective to superior categories; the diagnoses of the patients include severe neurotic behavior disorders, schizophrenia, autistic and symbiotic psychoses, character disorders, and chronic brain syndromes.

While a wide range of psychiatric illnesses being treated in one institution makes a need for heavy staffing, this same lack of specialization makes such an institution ideal for training students in all the disciplines involved in child care and treatment. A full and experienced staff adequately treating a wide range of problems is one essential of a good training program for psychiatrists, social workers, psychologists, students in special education, and child care workers. Providing such training is one of the functions of the Minnesota Residential Treatment Center.

Another of the multiple functions of the Treatment Center is consultation. Direct consultation is provided to the Department of Corrections for a variety of problems, from those termed "psychiatric emergencies," to aid

Continued

in long-term planning for particular children in custody. Direct consultation on matters of programming for child care is available to other institutions — those newly developing child treatment programs, for instance. For difficult diagnostic problems, especially those needing a period of study with the patient in residence, diagnostic services of the Treatment Center are available to agencies throughout the state.

Organization of staff and staff activities is based on the following assumptions about treatment: (1) a rational plan of psychiatric treatment requires thorough diagnostic study and skill in diagnostic formulation; (2) individual psychotherapy is one element of intensive treatment which takes fullest advantage of therapeutic possibilities in the shortest possible time; (3) greatest effectiveness in an intensive treatment program is attained when all the child's daily activities and contacts are attuned to the specific aims of a treatment plan arising out of the diagnostic formulation. Implicit in these assumptions is the view that residential treatment, even when lengthy, is an interlude in the patient's life, not a way of life.

The plan of psychiatric treatment for each child is the psychiatrist's responsibility. In addition to the medical director, who has over-all responsibility for all aspects of the program, two staff psychiatrist positions are allocated for the Treatment Center. (To date these two positions have not yet been filled so that the program is accordingly adjusted temporarily to the limits of what psychiatric staff work the medical director can do.) The work of the staff psychiatrists includes: (1) presiding at staffings; (2) direct psychotherapy; (3) supervision of psychotherapy; (4) psychiatric consultation to other staff members and to other institutions, particularly to the Minnesota Reception-Diagnostic Center, our next door neighbor in the Department of Corrections; and (5) teaching.

The psychology staff consists of a chief psychologist and two staff psychologists. Their responsibilities include: (1) diagnostic testing of children who are being considered for admission and of those who are about to have review staffing of their cases; (2) direct psychotherapy; (3) teaching; and (4) consultation to other staff members, especially on research and related matters.

The departments of child care and social service are under one department head. This permits better coordination of such things as planning visits from relatives with the scheduling of child care activities for the child, so that one doesn't become disruptive to the other. More important, it tends to keep child care from becoming an usurpation of parental responsibilities rather than a distinct discipline in an interdisciplinary treatment effort. There is a constant danger in residential treatment programs that the child's direct appeal to child care workers for help of every kind will make of the child care worker a parent substitute attempting to provide in myriad ways a new life with the promise of permanency. At the Treatment Center the person responsible for all child care is also responsible for the casework with parents. The aim of supporting parents in their parenting and in the hope of a child's return to family life is best served if parents correctly see the aim of child care in the institution as treatment and not as substitute home care.

The child care staff includes the department head already mentioned, two assistant supervisors, and forty-six child care workers. There are four cottages in the institution, two eight-patient living units to a cottage, or eight units in all. Each unit is staffed by four child care workers for three shifts. The children are grouped according to age, but on any one unit this may be the only common denominator; the range of intelligence and kinds of illness make individualization of care necessary. The living units are separated from each other geographically (except for the twin units which comprise a cottage) so that a child care worker cannot easily call on a worker in another unit for help in times of need for heavier staffing in his living unit. As a partial remedy for this, child care workers who are best qualified are designated "charge counselors." It is their duty to circulate among the cottages and provide help in many ways and to contact the assistant supervisors, the department head, or the director when they see the need.

The relevance of child care measures to the treatment plan is reviewed often in both scheduled and informal meetings with the two assistant supervisors and the department head, such meetings being the confluence of supervision and in-service training. The head of the department of child care is responsible for an in-service training program of lectures and discussions for child care workers. The lecturers are chiefly from the Treatment Center staff but there are also guest lecturers from outside the staff. Teaching and supervision are purposely fused; the department head and his two assistant supervisors work at welding usable concepts of psychiatry, psychology, and social work on the one hand to the practices of child care on the other so as to avoid the discontinuity between these which so often lies behind the woes of residential treatment centers.

The social work staff consists of the department head already mentioned and three staff social workers. They (1) interview parents or guardians to gather diagnostic information prior to a child's admission and also gather information from all other contributing sources; (2) work out with parents, or whoever is responsible for the child, what amounts to a contractual understanding, prior to admission, of what the Treatment Center can attempt as a feasible plan of treatment and what will be needed for such treatment in the way of involvement of parents in future interviews, visiting, trips home, provision for the child after he leaves the Center, etc.; (3) maintain from the beginning of the diagnostic study and throughout the treatment a liaison with whatever community resources will support a long-term plan for the child; (4) conduct scheduled interviews with the parents throughout the child's treatment at the Center, with aims and methods in keeping with the treatment plan for the child and the contractual agreement with the parents or others, utilizing in this interviewing whatever is known of the current issues in the child's life in the institution and in his psychotherapy; (5) convey to the rest of the staff the social worker's own understanding of what forces are operating within a family as this understanding develops; (6) conduct psychotherapeutic interviews with children as assigned by the director; (7) teach social work students.

Many of the children in residential treatment have not only dropped years behind in their academic education because of their emotional illnesses but have also not played sufficiently or interacted with others sufficiently in a secure environment to have developed ordinary skills or habits or graces which are usually taken for granted. Even if such children

Continued

could be "cured" overnight of their emotional problem they would still be seriously handicapped. At the Treatment Center, activities provided by a recreation worker, a music therapist, and an occupational therapist have as their aim the correction of these developmental lacks and distortions. The establishment for the child of a sense of rhythm, a sense of his own body, the satisfaction of using his muscles in an effective and graceful way and of coordinating his eyes and hands to accomplish something — these may be a "sine qua non" of treatment for an individual child and can accelerate treatment gains for many others.

The head of the activities department is also the head of the department of special education, having a background in both disciplines. Since few patients are able to attend public school the three teachers in the latter department provide teaching for almost all the children. Their focus is on academics and the attempt to further the child's pursuit of knowledge, to satisfy his curiosity and to give him what knowledge is considered useful in our culture, which is no different from the same attempt in the public schools. The teachers at the Treatment Center do not function as therapists using educational techniques but as teachers who are sophisticated about psychological and developmental issues.

The department head in charge of child care and social work and the department head in charge of special activities and special education are jointly responsible for translating the treatment plan that comes out of a staffing into specific programming for the child. An integrated program in terms of hours in cottage activities, in special activities, and in school, is devised in keeping with the treatment plan which is stated more generally, in terms of approach, aims, attitudes, and needs for certain kinds of experience.

General medical, dental and nursing care are provided for children from the Center and from the neighboring corrections institution by a physician, dentist and nurses accountable to the medical director. Appropriate clinics and hospitals outside the Center are used also.

The entire staff is involved in a program of staff development which is open as well to personnel from other institutions. The regular weekly scheduled exercises are made to serve, as far as possible, teaching functions in addition to getting the necessary staff work done. A weekly staff development meeting allows an opportunity for each staff member to present his point of view about what he does and what others do. Closely tied to the striving for the best possible treatment for each child is a program for continuous professional growth since ultimately, no matter what the organization of any program, therapeutic experience for the patients depends on the competence and morale of the staff.

Fred Kane, M.D.
Minneapolis, Minnesota

Editors Note: Because the Minnesota Residential Treatment Center is so limited in capacity (64 beds), all requests for admissions must be made by the County Welfare Department office and submitted to the Director of the Children's Mental Health Services for review.

Let thy mind's sweetness have its operation upon thy body, thy clothes, and thy habitation. — Herbert

Clinical Path Conference

Rectal Bleeding

This 49-year-old female entered the hospital because of rectal bleeding. Intermittent episodes of bright red rectal bleeding had occurred for one year.

Similar episodes had occurred twenty years earlier but had subsided to occasional episodes of spotting, until frank, painless bleeding associated with defecation was noted. Rectal pain "like little needles" also developed during the year. Anorexia, associated with weight loss of an unknown amount, was also present, and the patient had been unable to work for the preceding three months because of increased weakness. She was known to have hemorrhoids and was generally constipated. Some narrowing of her stools had apparently been observed for some time. Mineral oil was often taken and tended to produce diarrhea. There was no history of melena, food intolerance, abdominal pain or jaundice. Anemia had been diagnosed some years earlier and the patient had taken some iron pills.

Migratory polyarthritis had been present for four or five months, 15 years prior to admission. This was treated with injections of unknown medication. Pelvic inflammatory disease had been treated twenty years earlier by operation. Her last menstrual period occurred ten years prior to admission.

Physical Findings

Examination revealed a well-developed, anxious female in no distress, who complained of rectal pain.

The mucosae and nail beds were pale. The lung fields were clear to percussion and auscultation. The heart sounds were distant. The point of maximal impulse was at the fifth left intercostal space at the midclavicular line. M1 exceeded M2, and A2 exceeded P2. No murmurs were heard.

The costovertebral angles were nontender. The abdomen was soft, nontender, and tympanitic to percussion. No organomegaly was palpated. Bowel sounds were hyperactive. A cystourethrocoel and small rectocoel were found on pelvic examination. The cervix descended to the introitus with straining.

A small amount of pink fluid was present within the extremely tender anal canal. A circumferential stricture was palpated approximately 3 cm. above the internal sphincter. No masses were palpated and no external hemorrhoids were seen.

The blood pressure was 104/70 mm. Hg.; the pulse 112 per min.; the respiratory rate 16 per min., and the temperature 100.2°F.

Laboratory Findings

The hemoglobin was 9.5 gm. per cent; the white-cell count was 14,400 per cu. mm. Urinalysis was negative. The blood urea nitrogen was 9 mgm. per cent and the glucose 115 mgm, per cent. The electrolytes were within normal limits, as were the liver function studies, save that the albumin-globulin ratio was inverted, with the albumin level being 3.7 gm. per cent and the globulin level, 4.0 gm. per cent. An electrocardiogram was

Continued

unremarkable and a chest x-ray normal. A plain film of the abdomen showed a nonspecific pattern of gas within the small and large bowel.

Proctoscopy revealed some internal hemorrhoids and a stricture at 5 cm., beyond which the scope could not be passed. Bleeding from above this level was seen. Biopsies were taken.

A Frei test was negative. A barium enema revealed a 6-cm. area of deep, irregular, ulceration in the rectosigmoid. The descending colon appeared to be shortened and the sigmoid decreased in length. There was loss of haustral markings in the descending colon.

An intravenous pyelogram revealed a double collecting system at the right kidney but no other abnormality.

Progress

During this period the patient continued to bleed and received 1500 cc. of whole blood to raise her hemoglobin to 10 gm. per cent.

Operative Procedure

She underwent colon resection, including proctectomy, during the third week of this hospitalization. Her postoperative course was satisfactory and she was discharged from the hospital.

Readmission

She was readmitted to the hospital three months after her operation because she had become progressively weaker and had again begun to bleed from her distal intestinal stoma. She had also developed exertional dyspnea and dizzy spells.

Physical Findings

Examination at this time revealed a thin, wasted female, who was exceedingly lethargic. The lung fields were clear. Generalized abdominal tenderness was present. Hepatomegaly was noted. Bowel sounds were heard. A granulating wound was present at the perineum.

Laboratory Findings

The vital signs were similar to those of her previous admission, except that the temperature was now 101 degrees F. The hemoglobin was 7.5 gm. per cent and the white cell count 21,900 per cu. mm. The blood urea nitrogen was 7 mgm. per cent and the sodium was 138 mEq/liter, the potassium 3.3 mEq/liter and the chloride 105 mEq/liter. The CO2 was 31 mEq/liter. The thymol turbidity was 10 units, the cephalin flocculation test 1 plus and the total protein 6.8 gm. per cent, with the albumin 2.4 gm. and the globulin 4.4 gm. per cent. The prothrombin time was 15.8 seconds and the control 12.6 seconds. The calcium was 13.5 mEq/liter and the phosphorous 3.0 mEq/liter. The alkaline phosphatase was 12.9 King-Armstrong units.

A chest x-ray was normal. A plain film of the abdomen showed a moderate amount of gas within the bowel. An upper GI series was normal. A small bowel series suggested a possible fistula between the distal ileum and perineum. Five small areas in the left lobe of the liver showed no uptake of radioiodinated Rose Bengal, and the inferior border of the liver was markedly serrated.

Progress

The patient became increasingly lethargic and required tube feedings and supportive infusions of plasma.

Blood cultures and a lumbar puncture were unrevealing. Her urea nitrogen rose to 70 mgm. per cent.

She died quietly five months after her laparotomy.

Discussion

Dr. Harry Z. Mellins*

Any ulcerating lesion in the bowel can produce rectal bleeding; there aren't many lesions, however, which can cause both pain and bleeding. We can therefore narrow the field to lesions which produce stricture or a mass with ulceration. Also to be considered are lesions which may produce a mass associated with fissure formation and spasm. Similar episodes had occurred twenty years earlier but had subsided to occasional episodes of spotting, until frank, painless bleeding associated with defecation was noted at the beginning of the year. The question that arises is how similar were these episodes? This is a woman reportedly known to have had hemorrhoids, and one has to determine whether these were indeed similar episodes, or whether her earlier bleeding could have been due to her hemorrhoids. If one is to believe the history as given, then one has to think of a process that has continued for twenty years and then reached an acute terminus at this time. The history of constipation and narrowing of her stools tends to go along with the possible diagnosis of a stricture in the lesion. She had been known to be anemic, which, of course, would be associated with the bleeding. The past history I cannot find very helpful in evaluating the present illness. Except for the finding of a circumferential stricture 3 cm. above the internal sphincter, which we suspected from the history, physical examination was not especially striking. She was pale, with a very low grade fever and a slightly increased pulse, which would accompany her anemia, with perhaps some associated inflammatory process.

She had a hemoglobin of 9.5 gm. and her white count was slightly elevated. The blood urea nitrogen was within normal limits, but slight elevation of the glucose was present. Reversal of the albumin-globulin ratio was noted. At proctoscopy, which revealed some internal hemorrhoids, bleeding was seen to be coming from above the stricture. At this point we will turn to the films. Barium enema shows an area of narrowing in the rectosigmoid and sigmoid at least four inches in length. This area is irregular in outline, suggesting ulceration, and contains multiple small filling defects suggesting a polypoid lesion. The rectum itself seems small also and cannot be identified. There seems to be the edge of a tumor mass in the proximal portion of the straightened, shortened sigmoid. The evacuation film shows a normal mucosal pattern throughout the ascending and transverse colon, with a normal type of collapse. There is loss of the normal accordian-pleated collapse in the descending colon, with straightening of the descending colon. Differential diagnosis of this kind of straightening

Continued

is usually one of two things: a normal finding not uncommonly seen in people addicted to laxatives, or a sign of ulcerative colitis limited to the descending colon. The latter, however, is a somewhat dangerous diagnosis to make, because a good many normal people have this loss of haustrations. The air-contrast study also suggests that there is some rigidity with some loss of expansibility of the entire descending colon. Because of the findings present in the colon, the possibility of ulcerative colitis of many years duration, with superimposed malignancy, would have to be very strongly considered. This does occur in women of this age group and would account for a process which gives pain, bleeding and debilitation, with a 20-year history. Such malignancies metastasize early and widely.

The next possibility would be Crohn's disease of the colon (granulomatous colitis), which can be limited to the left side, although it is most frequently seen in the ascending colon and cecum. It usually causes diarrhea, rather than constipation, and generally produces a polypoid lesion, which would account for the rigidity and the shortening of the descending colon. Another possibility is linitis plastica of the colon.

Without clinical evidence of ulcerative colitis, we would assume that the appearance of the descending colon was a normal variant. Sarcomas of the colon occur but are quite rare. One of the lesions that occasionally occurs in the colon and that can cause anemia is lymphosarcoma. Syphilis seldom gives a local stricturing like this; it tends to involve the colon widely. Lymphogranuloma can cause such narrowing of the colon but is almost always associated with sinus tracts, and there are no sinus tracts visible here. We also have a negative Frei test. Schistosomiasis can involve the rectum and cause narrowing; it does not usually involve the sigmoid, however, and there are no other findings to suggest schistosomiasis.

In reviewing the small bowel, multiple small nodular filling defects were found on two different examinations. Now these nodules (intraluminal) are present on two separate small-bowel studies. Unfortunately one has to be very wary about diagnosing defects of this kind. It is desirable to fluoroscope the patient at the time one of these is seen and to spot-film it to be sure that it is not an air bubble. Inasmuch as these nodules appear on two different examinations, although they do not match up on the two, I am forced to consider that they may represent intramural or intraluminal nodules projecting into the lumen of the small bowel. If this is correct, we then have to consider what other lesions metastasize to the small bowel and give nodular densities. There are three common ones that do: melanoma, which may produce the so-called "target cell" metastases, when submucosal or subserosal implants ulcerate; lymphosarcoma; and some carcinomas. The other x-ray studies are not remarkable. The patient was operated upon and we are told that a colon resection, including proctectomy, was done, supporting the thesis that this was a wide-spread lesion that involved the rectum as well as the adjacent descending colon and sigmoid.

The remainder of her course does not require much discussion. Except that the potassium is a trifle low, the laboratory findings are not particularly helpful. Evidence of liver disease is present, with abnormal thymol turbidity, prothrombin time, and alkaline phosphatase values. Liver involvement is also suggested by the fact that there are five small areas in the left lobe of the liver which show no uptake of radioiodinated Rose Bengal and by the fact that the inferior border of the liver appears serrated.

Multiple hepatic abscesses might produce this picture. Wide-spread metastasis, however, is also suggested by the elevated calcium. We know that in disseminated malignancy, hypercalcemia may be found. There is no evidence of multiple bone lesions on the films available.

In summary then, I believe this patient had left-sided ulcerative colitis with malignant degeneration and metastasis to the small bowel and liver. Lymphosarcoma is a second possibility.

Pathology

Dr. Stanley Minkowitz*

Proctoscopy had revealed a stricture 5 cm. from the anal verge. This was hard to believe because examination of the biopsy specimen removed from this area contained epidermoid carcinoma. Epidermoid carcinomas usually occur either at the anal verge, or somewhat proximal to it, but very rarely at 5 cm., where the biopsy was reportedly taken, or at higher levels. Total colectomy with resection of the terminal ileum and proctectomy produced a specimen that measured 130 cm. The sigmoid was slightly shortened, but the length of the entire specimen was within normal limits. In the area of the splenic flexure, there was a small, ulcerated, saucer-shaped lesion that was very firm in consistency. The descending colon was somewhat narrowed, the most severe narrowing being seen in the sigmoid colon, the lumen of which was about one third normal in width. A little dilatation was

Continued

present in the rectal area. The mucosa of the rectum and the sigmoid was completely eroded, except where smooth, shiny, whitish linear discolorations were present. These represented leukoplakia or squamous metaplasia and were also present proximal to the lesions (Fig. 1). No pseudopolyps or "mucosal bridges" were seen and there were no signs of a chronic inflammatory process.

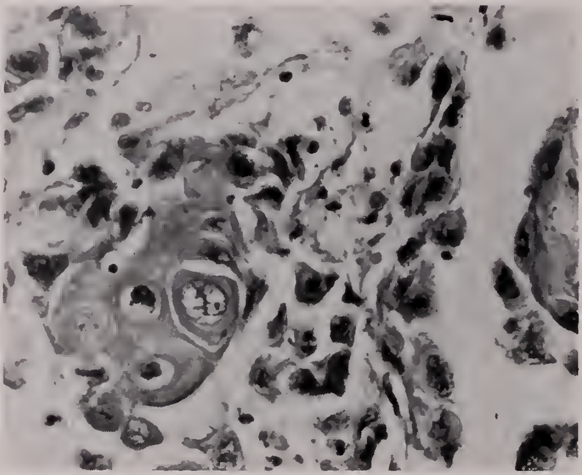

Fig. 2 — Squamous-cell carcinoma with pearl formation. Hematoxylin and eosin. X 100.

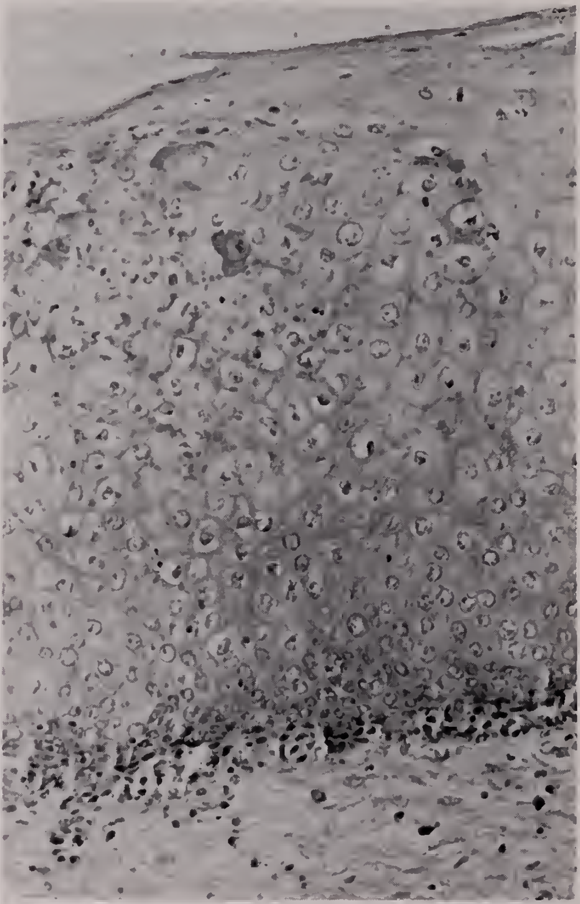

Fig. 3 — Squamous metaplasia in rectosigmoid area. Hematoxylin and eosin. X 40.

Microscopic examination of the lesion showed infiltrating malignant epidermoid cells forming pearls (Fig. 2), many of which contained large amounts of keratin and were arranged in nests. Some areas were moderately undifferentiated. Squamous elements within adenocarcinomas are not unusual; adenoacanthomas, for example, may be found in the bowel. A somewhat unusual finding in this case was the fact that there were no malignant adenomatous structures present. Associated with the squamous-cell carcinoma were areas of squamous metaplasia, in some areas of which the epithelium looked absolutely benign (Fig. 3), and in other areas of which, carcinoma in situ was present (Fig. 4). Outside the ulcerated areas, between the whitish areas containing the squamous metaplasia, normal colonic glands were present (Fig. 5). There are various theories concerning the etiology of these squamous cells. One theory is that they are ectopic rests, but this theory doesn't seem to be applicable in this case inasmuch as they are present over an extensive area. You wouldn't expect to find ectopic rests throughout the entire left side of the colon. The other theory is that they come from undifferentiated basal cells; but this theory is difficult either to prove or to refute. Another possibility in some adenoacanthomas of the bowel is that cells of adenocarcinomatous character become undifferentiated and then form squamous-type cells. In this case, however, there is no evidence of any adenocarcinoma. Probably the most likely theory is that these squamous cells represent a metaplastic phenomenon occurring within the adenomatous structures of the colon. What causes this metaplasia is unknown. It can be hypothesized that some sort of carcinogen has acted on the colonic mucosa to produce the squamous metaplasia and that further exposure to this material has caused the squamous-cell carcinoma of the rectosigmoid area. This happens to be an extremely unique case. I haven't found another in the literature exactly similar. Squamous-cell carcinomas of the right colon have been reported in two patients.[1,2]

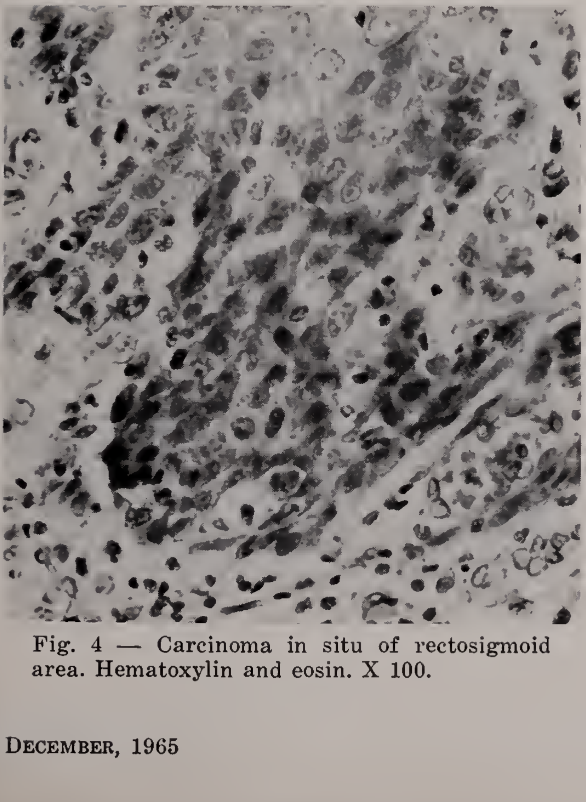

Fig. 4 — Carcinoma in situ of rectosigmoid area. Hematoxylin and eosin. X 100.

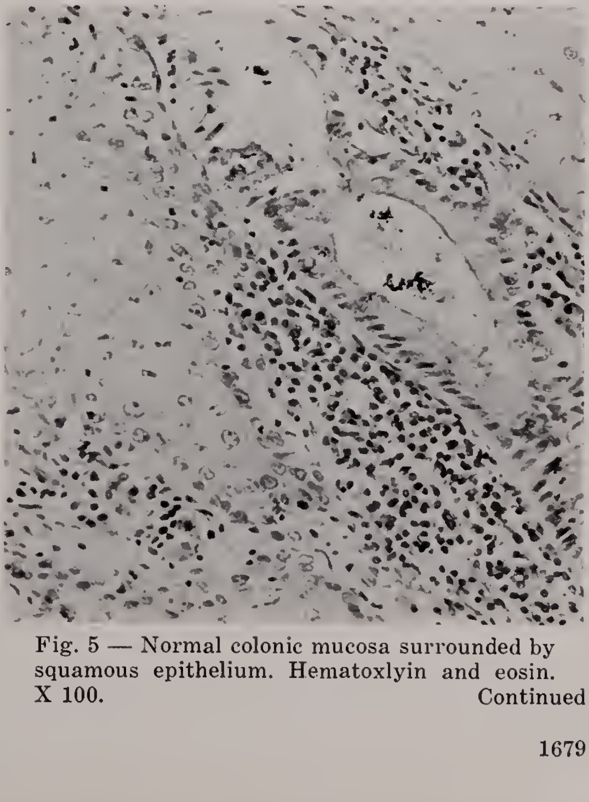

Fig. 5 — Normal colonic mucosa surrounded by squamous epithelium. Hematoxlyin and eosin. X 100.

Continued

As no autopsy was obtained at the time of the patient's death, we don't know whether or not there was small bowel or liver involvement by this neoplasm or any other process during her terminal period.

Final Anatomic Diagnoses

Squamous-cell carcinoma of the rectosigmoid with metastasis to the splenic flexure.

Extensive squamous metaplasia of the descending colon, sigmoid and rectum, with areas of carcinoma in situ.

"Skal noe gjøres, så få det gjort"
If something must be done, then get it done

Thus counsels an old Norwegian motto which reflects the attitude of a sensible people preconditioned by a rugged history to face facts and then take action. — THE AMERICAN SCANDINAVIAN REVIEW — Autumn 1965

Ramon Lull

In his Contemplation of God Ramon Lull (1235-1315) deplored the fact that doctors of the body are more sought after, better paid, more scrupulously obeyed than are physicians of the soul. They go well clad on good steeds, and amass wealth by working all sorts of impositions upon their patients, boasting of their knowledge of diseases of which they are really ignorant, prolonging the period of illness in order to increase their pay, and prescribing syrups and the like in large quantities because they share in the profits of the apothecaries. They try out potions on their patients which they would never take themselves, and there is no other art in the world so risky and over which there is so much disagreement.

Medical Conference

Diagnosis of Hyperparathyroidism

Dr. Richard Rosen*

During the past several months, we have encountered a number of patients with hyperparathyroidism. This symposium will present an interesting case that will serve as an introduction to a discussion of the diagnosis and treatment of the disease.

Dr. Carl Grosz**

A 31-year-old negro female was admitted to Kings County Hospital because of nonradiating epigastric pain of one day's duration. She had had a similar episode four months before which also lasted one day and subsided spontaneously. Her alcoholic intake consisted of one pint of gin per weekend. On admission, her blood pressure was 128/94, pulse 110, respiration 22 and temperature 99°F. The hemoglobin concentration was 14 gm.% and the leucocyte count 12,400 per mm^3. The serum amylase was 550 Somogyi units. Physical examination was unremarkable except for epigastric tenderness. X-rays of the abdomen were not helpful. She was treated for acute pancreatitis with nasogastric suction, intravenous fluids, tetracycline, Probanthine and analgesics. The following morning the serum calcium and phosphorus determinations were 14.5 mg.% and 3.5 mg.% respectively.

Dr. Richard Rosen

This patient was subsequently shown to have persistent hypercalcemia; her serum calcium levels ranged between 12.5 and 16.1 mg.%. This is presumptive evidence for hyperparathyroidism and indicates a need for further evaluation. The differential diagnosis should include chronic renal disease with secondary autonomous hyperparathyroidism, milk-alkali syndrome, sarcoidosis, vitamin-D intoxication, metastatic carcinoma, and multiple myeloma. Some of these entities are more common causes of hypercalcemia than of hyperparathyroidism. A normal intravenous pyelogram, serum creatinine, blood urea nitrogen and urinalysis ruled out primary kidney disease in this patient; normal gastrointestinal x-rays and lack of medication history ruled out vitamin-D intoxication and the milk-alkali syndrome. A normal chest x-ray and a negative steroid suppression test made sarcoidosis unlikely. The steroid suppression test, which can be helpful in evaluating hypercalcemia, consists of giving 10 mg. of prednisone four times a day for seven days and determining its effect on the hypercalcemia. In this patient, a bone survey was negative except for loss of the lamina dura of the teeth and, together with a negative steroid test

Continued

and a normal serum alkaline phosphatase, also made metastatic bone disease unlikely. The urine was negative for Bence-Jones protein, and bone-marrow examination and the serum electrophoretic pattern were normal, ruling out multiple myeloma. The factors in favor of a diagnosis of primary hyperparathyroidism included the persistently elevated serum calcium, hypercaliuria which persisted on a low calcium diet (urinary excretion of 328 mg. Ca per day on a 125 mg. Ca diet), no change in the serum calcium with steroids, loss of the lamina dura, and an abnormal tubular phosphate resorption test (TRP). Tubular phosphate resorption is perhaps not as well known as some of the other tests of parathyroid function. It can be determined from the formula.

$$\text{TRP} = \left[1 \frac{\text{Urinary P x Serum Creatinine}}{\text{Urinary Creatinine x Serum P}} \right] \text{x } 100$$

The normal is 82 to 95%, and a value under 60% is considered diagnostic of hyperparathyroidism. This patient had a value of 40%. Consequently, a neck exploration was performed.

Four parathyroids were easily identified and all were about three times normal size. Two of these glands were removed and the remaining two biopsied. Frozen sections confirmed that all four were parathyroid glands. It was thought that this was a case of primary parathyroid hyperplasia. On further exploration, another tumor was found: a large mass about 5 cm. in diameter, paratracheal and retroclavicular in location, projecting into the neck. This tumor was removed and also proved to be parathyroid tissue. The incidence of multiple parathyroid glands, that is, more than four, is well described in the anatomical literature and fairly well described in the pathologic literature; but it is seldom stressed in the surgical literature. Up to 12 parathyroid glands can be present normally; no good figures exist as to the incidence of an excessive number. Usually a surgeon, after identifying four, does not look for others. This case indi-

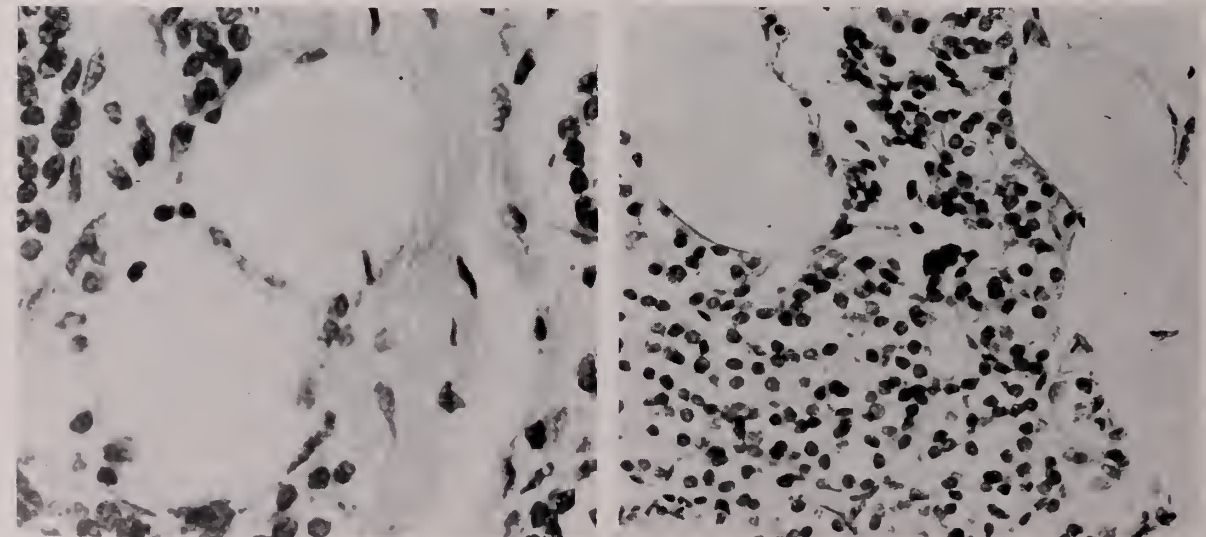

Fig. 1 (a) Biopsy of left superior parathyroid gland showing fat cells and chief cells. Hematoxylin and eosin. X 200. (b) Normal parathyroid with fat cells, clear cells and chief cells. Hematoxylin and eosin. X 200.

cates that a careful search of the neck and the available superior mediastinum should be made even when four parathyroids are identified.

Dr. Stanley Minkowitz*

The diagnosis of a normal parathyroid on biopsy is based on the finding of fat within the gland. This fat may be focal, and if an area containing fat is not included in the biopsy, the gland would look like a hyperplastic gland. A biopsy diagnosis of an adenoma is even more difficult. The diagnostic criteria require a rim of normal parathyroid around a circumscribed area of hyperplastic parathyroid and the finding of normal parathyroids elsewhere.

The case presented illustrates our problems. The right superior parathyroid was removed and was normal. The left superior gland was biopsied and reported as hyperplastic on frozen section, but the paraffin section revealed fat cells (Fig. 1a) ; however, the gland is normal, although enlarged. The left inferior gland was biopsied and was also normal (Fig. 1b). The right inferior gland was removed and was reported as hyperplastic, because no fat was seen; in addition, the large paratracheal gland that was described was removed. It measured 4 x 3 x 2 cm. and weighed 10 gm. Normally the parathyroids measure 0.5 x 0.4 x 0.2 cm. each and weigh about 35 mg. altogether. Grossly, this entity looked like an adenoma, but no rim of normal tissue could be identified, although sometimes there is so little normal tissue present that it can be difficult to find.

You can not predict the glandular function or history by the cell type. The main cell found in the parathyroid is the chief cell. This is a small cell type with a large nucleus and very little cytoplasm. The other cell types are supposed to originate from this chief cell. If it contains much

---

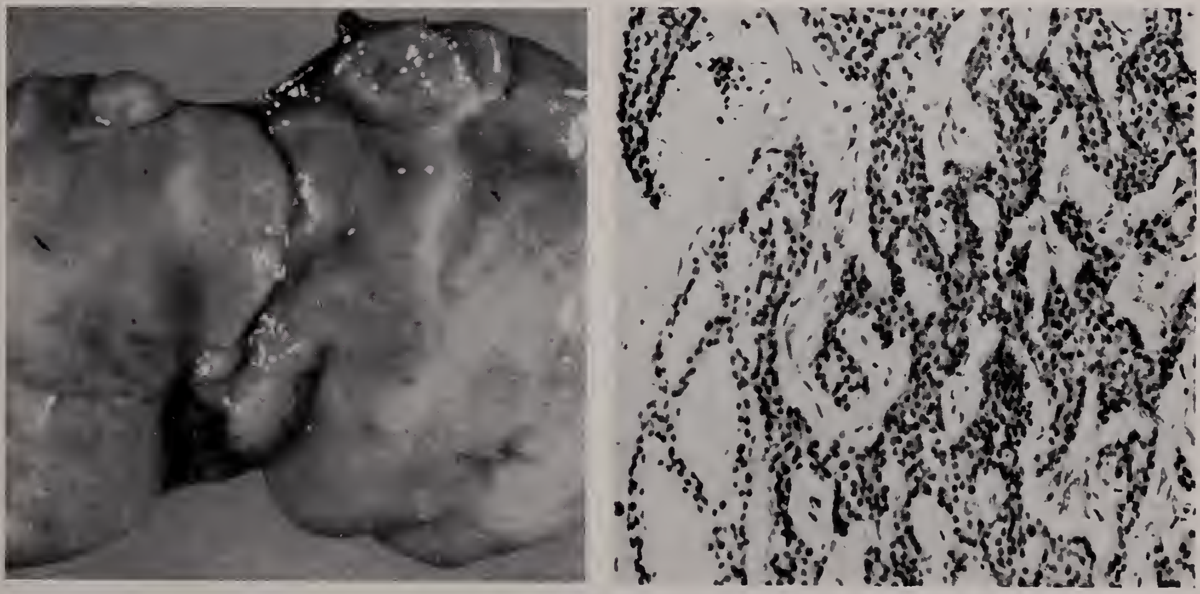

Fig. 2 (a) Cut surface of the parathyroid adenoma. Gross picture. (b) Microscopic picture of the adenoma. Hematoxylin and eosin. X 200.

clear cytoplasm it is called a clear cell or Wasserhelle cell. If the cytoplasm becomes eosinophilic it is called an oxyphil cell, which is supposed to be nonfunctioning.

In this case, then, we have two parathyroids removed that were hyperplastic, one that was normal, and two biopsied that were normal. I think that this probably represents two adenomas rather than hyperplasia.

Dr. Carl Grosz

Mixter and Cope collected 62 patients from the literature with hyperparathyroidism and pancreatitis. In their own experience, 7% of patients with hyperparathyroidism had pancreatitis or pancreatic calculi. Very few of these were alcoholics. Fifteen of the 62 patients died of pancreatitis, indicating the seriousness of this complication. The calcifications seen on abdominal roentgenograms are usually in the ductal system. McPherson has given animals large doses of parathormone and has observed calcium deposits in the omentum, but he was unable to reproduce the pancreatic ductal calcification.

Dr. Stanley Wallach*

Hyperparathyroidism is a disease which dates from antiquity, and it is often forgotten that the isolation and purification of the hormone was not accomplished until about five years ago. Since that time a great deal has been learned. Parathormone is a polypeptide with a molecular weight of about 9,000 and has a multiplicity of actions. The main purpose of this hormone is to maintain serum and extracellular calcium concentrations at levels which will provide sufficient calcium to the cell for normal neuromuscular and cardiovascular function, endocrine and exocrine secretion, mitochondrial function and other physiologic and biochemical processes.

The hormone has at least three recognized actions on calcium metabolism. It causes the resorption of previously formed bone by converting osteocytes and osteoblasts to osteoclasts which presumably produce metabolic acids capable of dissolving bone. The calcium so released provides a supply for the maintainence of the plasma calcium level. The hormone also increases gastrointestinal absorption and renal tubular reabsorption of calcium. The phosphaturic action of the hormone, which is effected by decreasing phosphorus reabsorption by the renal tubules, can be considered ancillary to the hormonal action on calcium metabolism. When bone is resorbed, both calcium and phosphorus are released; if the latter accumulated in the extracellular fluid, calcium phosphate complexes would be formed which would be readily shunted to soft tissues and bone. Therefore, the hormone's ability to maintain plasma and extracellular calcium concentrations is limited by a high phosphorus concentration. The plasma and extracellular calcium concentrations determine the amount of calcium transported across the cell membranes of the parathyroid gland, and this controls the synthesis and/or secretion of the hormone. There is little evidence that a trophic effect is exerted by the pituitary or that any influences other than calcium levels control parathyroid secretion. The suggestion has been made that hyperparathyroidism may have its origin in previous hypocalcemia which causes increased parathyroid activity and eventual adenoma formation or autonomous hyperplasia. Pancreatitis is occasionally accompanied by low plasma calcium concentrations, and it has been suggested that pancreatitis may be such a stimulus; but there is little evidence to support this belief.

---

*Assistant Professor of Medicine, State University of New York, Assistant Attending Physician, Kings County Hospital Center.

Clinical Manifestations

There are seven clinical modes of presentation of hyperparathyroidism, but only two are common. 1. *Renal calculus formation* occurs in about 70% of cases and develops primarily because of the presence of high urine concentrations of calcium. There is some evidence that a second factor may also promote renal calculus formation. When bone resorption occurs, not only is calcium released but bone matrix is destroyed. Mucopolysaccharides and glycoproteins similar to those found in bone matrix appear in the urine in hyperparathyroidism, and there is evidence to suggest that these may cause nucleation and, eventually, calculus formation. Occasionally, the urine calcium is not high in hyperparathyroidism; when it is not, renal calculus formation usually does not develop. If renal insufficiency has occurred, the filtered load of calcium may be normal or subnormal. In other cases, since the hormone increases tubular reabsorption of calcium, the excretion of calcium may be normal even if the filtered load is high.

2. A second common mode of presentation of hyperparathyroidism is illustrated by today's patient. *Upper gastrointestinal symptoms* occur in about 25% of cases. About 10% have peptic ulcers and about 5%, pancreatitis. An additional 10% have symptoms suggestive of one or the other, but no gastrointestinal pathology can be demonstrated. The cause of an increased incidence of peptic ulcer in hyperparathyroidism is unexplained. As for the pancreatitis, ductal calculi are common in patients with coincident hyperparathyroidism and pancreatitis, and possibly increased amounts of calcium are secreted by the pancreas with the development of calculi and reflux pancreatitis. A second possibility is that calcium, as an activator of trypsin activity, may cause intracellular activation of trypsin with a resultant pancreatitis.

The five remaining modes of presentation are rare. 3. These include the development of *bone manifestations such as pain, pathologic fractures, giant cell tumors and bone cysts;* the osteitis of hyperparathyroidism. 4. *Neuromuscular symptoms such as fatigue, lethargy, psychosis or coma may develop.* Calcium is a stabilizer of neuromuscular cell membranes, and with high plasma calcium concentrations, a considerable diminution in neuromuscular irritability may be present. 5. *Polyuria and polydipsia* may occur, due to an inability to concentrate the urine. 6. *Renal insufficiency* may appear, due to nephrocalcinosis. The nephrocalcinosis may not be obvious by x-ray, and microscopic nephrocalcinosis can cause extensive renal damage. 7. *Hypertension* is present in 50 to 70% of patients with hyperparathyroidism but is only rarely the presenting symptom. In about half the patients who have hypertension and hyperparathyroidism, there is sufficient renal disease present to explain the increased blood pressure. In the remainder, it has been suggested that a calcium-mediated increase in vascular smooth muscle tone is involved. Calcium is not only a stabilizer

Continued

of neuromuscular membranes but a direct stimulator of muscular contraction.

Diagnosis

The diagnosis of hyperparathyroidism requires three criteria: 1. the presence of a proper clinical setting: at least one of the seven described and preferably one of the first two; 2. hypercalcemia, either persistent or transient; and 3. elimination of other causes of hypercalcemia. On rare occasions, patients with proven parathyroid adenomata have not met all three criteria. The one that is usually not present is hypercalcemia. The present patient's plasma calcium fluctuated between 12.5 and 16 mg.%. If a lesser degree of hyperparathyroidism were present with a maximum plasma calcium of 13 mg.%, fluctuation between 10 and 13 mgm.% could have occurred. If one were so unfortunate as to evaluate such a patient at the wrong time, diagnosis might prove difficult. If renal disease has intervened, not only may urine calcium excretion be diminished, but plasma calcium concentrations may decrease as the serum phosphorus rises due to phosphate retention. It has also been suggested that some of these tumors might secrete calcitonin as well as parathyroid hormone and the two counteract each other with regard to plasma calcium levels. However, this possibility is highly speculative.

Dr. Michael Golding*

Nonparathyroid tumors have been implicated in high blood parathormone levels. What is the incidence compared with primary parathyroid gland involvement and when should one search for these as the cause of hypercalcemia?

Dr. Irving Enquist**

I would say that any of the extracervical tumors that elaborate parathormone are quite obvious and therefore should be detected by a good work-up. They are usually renal, pulmonary, retroperitoneal, adrenal, or of unusual types. I think their incidence is much less than primary parathyroid tumors as a source of elaboration of parathormone.

Dr. Henry Schnitman†

In the case presented, do I assume correctly that it was a large adenoma?

Dr. Richard Rosen

Well, it's a matter of interpretation. There was one very large adenoma and there was another enlarged parathyroid which might have been an adenoma. There were also normal parathyroids.

Dr. Schnitman

This fact confuses me. Usually, when you find one adenoma, the other glands are hypoplastic.

Dr. Enquist

I feel the same way Dr. Schnitman does. If you have an adenoma, the remaining glands should be normal and small. Logic supports this. However, we recently had a patient whom we explored and in whom we found one perfectly normal gland. A second gland was large, and we thought it was an adenoma until Dr. Minkowitz found it on frozen section to be full of fat. Finally we found another parathyroid gland which we removed and which was in fact an adenoma, no more than 5 mm. in maximum size.

The Tobacco Tyrant*

Witthaus & Becker's Toxicology reports: "Tobacco enemata were formerly frequently used, and have caused a number of poisonings, several of which have resulted fatally. Severe and even fatal poisonings have been caused by administrations and decoctions of infusions of tobacco "pipe oil" by the mouth as popular remedies for various disorders, or to provoke abortion; by the use of food articles accidentally contaminated with tobacco; by water saturated with tobacco smoke given to a child to induce quietness; by chewers or "dippers" swallowing the juice; by children sucking foul tobacco pipes; by the application of tobacco to abraided surfaces, and even to uninjured skin; and by excessive smoking."

Osborne says: "The most serious disturbance caused by the abuse of tobacco is on the heart. While smoking may temporarily slow the pulse, soon, with a weak heart, the rapidity is increased and very soon the heart-action is frequent. While smoking, the blood pressure may be increased, with excessive use it is soon diminished. The heart may be irregular or intermittent, and there may be actual dilatation of the heart, and an insufficiency of the mitral valve, entirely due to the over-use and over-action of tobacco. Tobacco heart is recognized as a condition which can generally be cured by withholding tobacco."

Neuhof observed several cases of extrasystoles (usually auricular), one case of flutter, and one of fibrillation. He also reports in detail a case of sino-auricular block.

To be continued next issue.

for the comprehensive control of the pain cycle

TRANCO-GESIC®

CHLORMEZANONE with ASPIRIN

100 mg. 300 mg.

NON-NARCOTIC ANALGESIC, with tranquilizing and muscle relaxant properties

Because pain is frequently aggravated and perpetuated by both anxiety and muscular tension, the combination of aspirin with a well tolerated tranquilizer—muscle relaxant (Trancopal® (brand of chlormezanone)) is exceptionally effective.

TRANCOPAL is a "Tranquilaxant" which calms anxiety and tension, relieves muscle spasm, and enhances the analgesic effect of aspirin by subduing *emotional responses* to pain.

In low back pain

sciatica, lumbago; musculoskeletal pain associated with strains and sprains

In tension headache

premenstrual tension and dysmenorrhea

Side effects such as gastric distress, occasional weakness, sedation or dizziness may be noted. Ordinarily, these may be reversed by a reduction in dosage or temporary withdrawal of the drug. TRANCO-GESIC should not be administered to persons known or suspected to have an idiosyncrasy to acetylsalicylic acid.

Dosage for adults is usually 2 tablets three or four times daily, the suggested dosage for children from 5 to 12 years is 1 tablet three or four times daily.

Supplied in bottles of 100 and 1000 tablets.

Grand Rounds

Pharmacotherapy of Sural Thrombophlebitis*

Since no thoroughly reliable means of prevention of venous thrombo-embolic disease exists, the major concern of the physician or surgeon remains the management of the established case and the prophylactic institution of therapy in those patients with known predisposition to venous thrombo-embolic disease. Until such time as the hospital laboratory can detect the presence of abnormal venous clotting, the appraisal and management of patients harboring venous thrombi must remain at the clinical level. Improvement in the use of present chief therapeutic methods, anticoagulant drugs, and venous division can result only from studies of treated cases, with particular emphasis on therapeutic failures.

Treatment

Before treatment is instituted the attending physician should have the goals of such therapy clearly in mind. These are:

1. Prevention of pulmonary embolization.
2. Prevention of clot propagation.
3. Prevention of chronic venous insufficiency.
4. Relief of the acute symptoms of thrombophlebitis.
5. Prevention of thrombus formation elsewhere.
6. Lysis of the thrombus already present.

Presently accepted methods of treatment utilize the following in attempting to fulfill the above goals:

1. General measures aimed at relieving acute symptoms.
2. Anticoagulant drugs
    a. Heparin
    b. Antiprothrombin agents
        1. Coumarins
        2. Indonedione compounds

---

*The term thrombophlebitis as used in this presentation shall refer to the syndrome of a thrombus within the lumen of a vein with antecedent, concomitant or subsequent reaction of inflammation around and within the involved vein wall and thrombus.

Presented as a Medical Grand Rounds at Mt. Sinai Hospital, Minneapolis, May 25, 1965.

Continued

3. The use of fibrinolytic agents
4. The use of IV Dextran
5. Venous ligation in selected cases
6. Anti-inflammatory agents

General Measures

There seems to be almost universal agreement that general measures supplemented with one or more of the above specific measures have a definite and established place in any treatment program. These are utilized primarily to obtain relief of acute symptoms due to thrombophlebitis. They include bed rest, elevation of the affected extremity, local application of heat, and analgesics. In most instances, these are quite effective in relieving symptoms within 12 to 48 hours. Position in bed is important in promoting drainage of venous blood. The affected limb should be at a level higher than the thorax. Patients sitting with the head of the bed and affected limb elevated in the so-called "jack-knife" position have venous blood pooling in the pelvic veins, which may promote pelvic vein thrombosis. Local application of moist heat to a limb affected by thrombophlebitis aids in relief of pain and perhaps also by dilating the superficial venous system, thereby increasing the collateral vein channels. Analgesics such as aspirin, codeine and drugs of similar potency almost always suffice to relieve patients of discomfort.

Certain cautions are in order, however, when using the measures described above.

1. In patients with ischemic limbs and concomitant thrombophlebitis heat must be used with caution, if at all.
2. Elevation of an ischemic limb is usually contraindicated.
3. Drug and skin sensitivities must also be taken into consideration.

Anticoagulant Agents

Before the institution of anticoagulant therapy, it must be ascertained whether or not contraindications exist. These are listed by Estes as:

Absolute

a. Any blood dyscrasia which has purpura or hemorrhage as a manifestation.
b. Subacute bacterial endocarditis.
c. Recent brain or spinal cord surgery.
d. Recent major G.I. bleeding.
e. Laboratory facilities which are inadequate to provide accurate plasma prothrombin time determinations when the coumarins are used.
f. A physician who is untrained or inexperienced in anticoagulant therapy.

Relative

These situations call for increased caution and include the following:
a. Hepatic insufficiency.
b. Renal insufficiency.
c. Indwelling tubes (GU, GI, etc.)
d. Esophageal, gastric or duodenal ulcer, without recent bleeding therefrom.

e. Granulatory wounds, skin ulcers or potential bleeding sites.
f. Obstruction to biliary flow.
g. Severe nutritional or vitamin deficiency.

History

With the discovery of heparin by McLean in Howell's laboratory at Johns Hopkins University in 1916, there began a new era in the treatment of thrombo-embolic disease. Initially, heparin was only a research drug because of its impurity which caused severe reactions. Nearly 20 years passed before Best and his associates in Toronto produced a purified and concentrated product suitable for use in man. Clinical use of heparin began with the trials of Murray in Toronto in 1935 and with those of Crafoord in Stockholm in 1936. From this point on, heparin gained wide usage for the treatment of thrombo-embolic disease.

In the winter of 1921-22, veterinarians in the province of Alberta, Canada, and in North Dakota reported a new disease in cattle, "Sweet clover disease," characterized by excessive and sometimes fatal bleeding after trauma or surgery (castration, dehorning, etc.). In 1934, large scale experiments on the disease were initiated at the Wisconsin Agricultural Experiment Station under the direction of Link and Campbell and their associates. This work was greatly accelerated by the development of a quantative method for prothrombin determinations by Quick and coworkers. The active principle was finally obtained in pure form by Campbell and Link in 1941 and identified chemically as 3,3:methylene-bis (4-hydroxycoumarin), the only biscoumarin derivative found in nature. It is of interest that the same chemical had been synthesized by Onschutz in 1903. In 1934, Morawitz suggested that thrombosis could be prevented if a nontoxic agent could be found which would selectively and reversibly impair the production of prothrombin by the liver. Such an agent obviously had become available in bishydroxycoumarin. Meyer and Bingham and their co-workers at the University of Wisconsin and Butt and Allen and their associates in the Mayo Clinic conducted the first human experiments in 1941. Since this trial, these compounds have been extensively used in thrombo-embolic diseases.

The use of fibrinolysin, low molecular weight dextran, and anti-inflammatory agents is a fairly recent occurrence. Their value has not been fully demonstrated and they do not have an established place in the treatment of thrombo-embolic disease at present.

Mechanism of Action

Heparin

Heparin inhibits or prevents the clotting of blood both in vitro and in vivo. Therapeutic doses prolong the clotting time but do not affect the bleeding time. Heparin exerts at least four somewhat interrelated effects on the clotting mechanism of the blood:

a. It acts as an antiprothrombin to prevent the conversion of prothrombin to thrombin.

b. It quantitatively antagonizes thromboplastin by a mechanism not fully understood.

c. It prevents thrombin from reacting with fibrinogen to form fibrin.

Continued

d. It prevents agglutination of platelets, probably by preventing thrombin formation.

In addition to the anticoagulant properties, heparin possesses other actions. The most pertinent to this presentation is its anti-inflammatory effect.[1]

Coumarins

Bishydroxycoumarin affects blood coagulation by causing hypoprothrombinemia. The mechanism by which the compound inhibits prothrombin production has not been fully elucidated, but indirect evidence strongly suggests that it interferes with the role of Vitamin K in the liver synthesis of prothrombin. It is thought to produce this effect by competitive inhibition for the apo-enzyme essential for prothrombin synthesis.

Dextran

Dextran administered by intravenous infusion has been used by several investigators in molecular weights varying from 40,000 to 120,000. The proposed mechanism of action is threefold[3]:

a. It coats erythrocytes increasing the electronegativity of the cells and prevents sludging.

b. It coats the internal surface of vessels, decreasing the current of injury and thereby the agglutination of platelets at the site of internal damage.

c. It increases the peripheral blood flow.

Fibrinolysin

Commercial preparations currently contain both profibrinolysin (plasminogen) and an activator of streptokinase to bring about the conversion of plasminogen to plasmin.[4] Therefore, we don't really know if the foreign plasminogen is being activated or if the body's own fibrinolytic system is being stimulated. Clinical studies are few at present, with almost equal results using both in combination or streptokinase alone.

Anti-inflammatory Agents

Phenylbutazone is the only such agent frequently used in thrombophlebitis. It has no known anticoagulant effect and exerts only an analgesic, antipyretic action inferior to that of common aspirin.[1]

Clinical Studies

Sawyer[5] and associates conducted a study to compare the effects of conservative management, heparin therapy and fibrinolysin therapy. They had a total of 43 patients with acute sural thrombophlebitis. Selection of patients for therapy was done by randomized envelopes. Usual historical and physical findings supplemented with immediate bilateral phlebography were used for diagnosis. Patients were excluded from the study if they had had symptoms for longer than 48 hours.

Patients in Group A received only symptomatic treatment, plus penicillin (1 million units twice a day) and streptomycin (0.5 gm. twice a day). Group B received, in addition, heparin intravenous 50-75 mg. every four hours. Group C received 50,000 to 100,000 units of intravenous Thrombolysin (plasminogen and streptokinase) every two hours.

Patients in Group B had a significantly more rapid symptomatic recovery than those in either Group A or C. There was no pulmonary embolization in Group B but two deaths in Group A and three in Group C from pulmonary emboli.

It was not possible to use days of therapy to ambulation and discharge because of an obligatory 12 to 14-day bed stay before post-treatment phlebograms could be performed.

Seven hundred and forty-four (744) cases of thrombo-embolic disease, occurring over a 10-year period at the Massachusetts Memorial Hospital, were reviewed.[6] Patients were randomly selected and treated with heparin alone, intramuscularly, intravenously or subcutaneously, bishydroxycoumarin alone, heparin and bishydroxycoumarin. The authors conclude that intermittent intravenous heparin therapy carried out for a minimum of 10 days is the treatment of choice. Dicumerol appears to have little to offer in the therapy of the acute case from the standpoint of prevention of pulmonary embolization, prevention of recurrence of thrombotic process, or speed of subsidence of the inflammatory process.[7,8]

Carey and Williams[9] produced experimental thrombi in dogs by applying a small direct current to the surgically exposed external jugular vein. They concluded that propagation is prevented if the Lee White time is 1½ pretreatment value. Propagation was not prevented by dicumerol or tromexon unless prothrombin time values well below 20% were maintained.

Since October 1, 1940, 947 cases of deep venous thrombosis have been treated with intermittent intravenous heparin at the General Hospital in Mariestad, Sweden.[10] The patient was not disturbed at night, and no Lee White clotting times were performed. This dosage was continued until the patient was free from thrombophlebitis symptoms (average 4.42 days). He was then given 150 mg. of heparin and ambulated. If no recurrences of symptoms occurred during ambulation he was treated for an additional day and allowed to leave the hospital wearing an elastic stocking on the affected leg. In the entire series, the incidence of pulmonary embolization was 0.9% with seven deaths. There was a recurrence rate of 2.4%. A slight hemorrhagic tendency was observed in only 14 cases (a rate of 1.5%). None of these patients required more therapy after withdrawal of heparin.

Studies by Moncrief[3] and Cox et al. with dextran appear to be very promising but are presently very limited and still at the experimental stage.

Conclusions

There seems to be general agreement that intermittent intravenous heparin is the drug of choice in the treatment of acute sural thrombophlebitis. Although some will object to the cost of heparin (average $10 per day), the money saved the patient by reduced hospital stay and decreased incidence of complications will more than offset this objection. From the current work being done with dextran, this appears to have the

Continued

potential of replacing heparin as the drug of choice. However, more clinical studies will have to be performed in order to accomplish this.

For Eye Disorders in Ancient Egypt

The Ebers Papyrus of ancient Egypt dealt comprehensively with diseases of the eye; from blepharitis to trichiasis; prescriptions for casual and minor eye disorders abounded.

For bleary eyes an extraordinary concoction of onions, myrrh, verdigris, cypress-from-the-north, antelope dung, oil, and entrails-of-the-qadit-animal was recommended — to be painted on the eye with a vulture's feather. Since, however, antelopes, qadit-animals, and vultures were beyond the financial reach of most Egyptians — pharaohs and plutocrats excepted — the proletariat could substitute the lowly, versatile, and ubiquitous ass. In fact, just one ass's tooth alone would avail — provided it was well-wet with water and applied all around the bleary eye.

For bloodshot eyes one remedial procedure consisted of alternately bathing the eyes in two separate mixtures: one consisting of Fruit-of-the Dompalm and Milk-of-a-Woman-who-has-borne-a-Son, and the other — anticlimactically — of Cow's Milk.

Squinting was overcome by applying a salve of equal parts of Tortoise-brain and abra-ointment.

Hot eyes could be relieved by mixing Tallow-from-the-Jawbone-of-an-Ass with Cold Water and applying it to the — temples!

Finally, Xanthelasma succumbed to a 50-50 compound of Red-lead and Goose grease smeared on the eyes, to which unique prescription the Scribe appended the rather cryptic exhortation: SEE TO IT!

As a man gets older, he suspects that nature organized him for the benefit of the dentists and doctors. — Anon

Collagen Synthesis and Lysis

in Healing Wounds

IRVING F. ENQUIST, M.D.*
ROLAND J. ADAMSONS, M.D.**
Brooklyn, New York

THE MOST important biochemical change occurring in a healing wound is the synthesis and orientation of collagen fibers by fibroblasts. Production of collagen is the end result of a host of complex chemical reactions, many of which are little understood. Most attention has been directed at collagen synthesis and its subsequent maturation, and only recently has another aspect of collagen metabolism been recognized. It is now apparent that collagen is actively lysed during several phases of, if not throughout the healing process. Our purpose in this presentation is to summarize briefly the present knowledge of collagen synthesis and collagen lysis and their respective roles in the achievement of total wound healing.

Collagen Synthesis

Collagen Content vs. Tensile Strength

Dunphy and Udupa[1] measured the synthesis of collagen in granulation tissue of skin wounds in rats and related the concentration of collagen in these wounds to the tensile strength of healing, sutured skin wounds in different animals of the same species. During the lag phase the wounds showed no increase in collagen; but since there was a proliferation of fibroblasts and a marked increase in ground substance, Dunphy called this the "substrate phase." These changes were necessary precursors for those which immediately followed. With the end of the lag (substrate) phase the collagen content of the granulation tissue increased rapidly until the fifteenth day, at a rate very similar to the rate of gain in tensile strength of sutured wounds. These studies were done in normal animals.

Vitamin C Influence

Dunphy and his group[2] then showed further that Vitamin C deficiency resulted in a decreased collagen production in granulation tissue and that this corresponded to the known impaired healing of incised wounds in scorbutic animals. The direct relationship between collagen synthesis and tensile strength was thus established. However, Grillo and Gross[3] soon showed that contraction of open skin wounds in scorbutic animals was unimpaired. Also, in animals with alloxan diabetes Rosen and Enquist[4] found no impairment in the contraction of skin

State University of New York.

wounds, although the gain in strength of sutured wounds was markedly impaired. Both of these studies suggested that the mechanisms responsible for the healing of open tissue defects are different from those involved in the healing of sutured wounds. Therefore the study of the relationship of collagen to tensile strength will be more appropriately made if the two parameters are studied in the same wound.

With this background Rosenthal et al.[5] studied absolute collagen concentrations and tensile strengths of incised wounds in normal and alloxan diabetic rats. The wounds in poorly-controlled diabetic animals healed significantly more slowly than those in normals, but there was no difference in the collagen content of the wounds. Furthermore, Peacock[6] demonstrated that secondarily closed wounds healed faster than primary wounds of the same age, despite lower collagen concentrations. He postulated that although collagen is responsible for tensile strength, the biochemical and biophysical properties of the fibers are more closely related to tensile strength than are the absolute local concentrations. Gain in strength of wounds during the late or maturation phase is due to remodelling and increased cross-linking of collagen fibers, without any absolute increase in number.

Wound Collagen Excess — Positive or Negative

The studies cited above were made in small laboratory animals, all of whom showed marked and rapid changes in the collagen content of their musculature from any major stress — operation, bacterial infection, metabolic disorder, etc. The changes in muscle collagen under these circumstances are explained by a marked tissue catabolism leading to reduction of all cellular elements except the collagen framework, which then remains at a relatively higher local concentration. This is confirmed by the inverse relationship between body weight and muscle collagen seen in small laboratory animals after wounding. The total body collagen pool is apparently unchanged. For these reasons, examination of wound collagen *per se* is an inadequate indicator of collagen metabolism. The collagen concentration of a wound is a reflection of local collagen synthesis, local collagen lysis, and the changes resulting from systemic changes affecting the entire organism. To determine local collagen synthesis, one subtracts from total wound collagen the collagen concentration of unwounded muscle at a comparable region of the body. This difference is the "active" collagen, elaborated at the wound site for healing. We have labelled the fraction the "wound collagen excess."[7-9] When the "wound collagen excess" is positive, the wound is stronger than unwounded contralateral muscular wall; when the "wound collagen excess" is negative, the wound has negligible inherent strength. This is clearly demonstrated in healing incisions in normal and scorbutic animals and persists for about 15 days after wounding.

Collagen Lysis

In a a number of experiments we noted that healing, incised wounds were weaker on the third day than on the first or second days after wounding. Examination of collagen then showed that the wounds regularly — on the third day — contained less collagen than unwounded muscle; i.e., the "wound collagen excess" was negative. We postulated that active lysis of collagen was occurring on the third day, the end of the lag phase. Study of wounds during the late or maturation phase revealed the same phenomenon, but less pronounced. It is our view that the lysis of collagen during the lag phase involves old collagen already present in the tissues, but that the lysis occurring late is destroying newly-synthesized fibers.

Enzyme

Collagen has been considered a relatively nonreactive protein participating slowly in the body metabolism; but it is now obvious that the enzymes capable of breaking down collagen had to be present in the tissues. Decrease of collagen has been shown in areas of granulomatous inflammation and in necrotizing skin inflammation produced by croton oil injection.[10] Lapierie and Gross[11] identified and measured a collagenolytic factor produced by the soft tissue in tadpole tail, and differentiated it from other proteolytic enzymes. Collagenolytic activity was also shown to occur in the metaphysis of long bones by Walker, Lapierie and Gross.[12] Activity was increased five to tenfold with parathyroid extract. Homogenates* of postpartum rat uteri contained five times as much collagenolytic activity as homogenates from nonpregnant uteri.[13] The discovery of this enzyme helps to explain the rapid decrease in the size of the uterus immediately post partum. Peacock[14] demonstrated nicely in his studies of the healing of tendon grafts that selective lysis and remodelling of deposited wound collagen played a vital role in the differentiation of scars, particularly in the restoration of gliding function in tendon grafts. He demonstrated microscopically the disappearance of fibrous adhesions and suggested that at some time during wound healing the production and lysis of collagen come into equilibrium. All of the work cited above gives adequate proof that collagen is readily lysed by mammalian tissues, and a number of our own studies lend support to this view.[7-9]

Inflammation

Because inflammation has been shown to cause lysis of collagen, and because catgut sutures are reported to cause a more vigorous inflammatory reaction than silk[15] we predicted that wounds closed with catgut would show a greater lysis of collagen than wounds closed with silk. However, under the ideal healing conditions of our experiment, we found no difference in collagen lysis between the silk and catgut wounds.[7] We therefore concluded that the amount of tissue in the inflammatory reaction about the sutures was insufficient to affect collagen lysis. It must be emphasized that this observation is valid only for wounds healing under ideal conditions and is not applicable to wounds with impaired healing.

Collagen lysis during the lag phase is seen in only a very narrow zone along the incision, with maximal collagen resorption occurring in the area between the incision and 1.85 millimeters away.[9] On the third day this narrow strip contains 89% of the collagen present at the time of wounding. In the next zone (1.85 to 3.7 mm. from the incision) lysis of collagen is less active. We have no knowledge if these changes which occur during the lag phase are also occurring throughout the healing period; however, during the later stages (after the tenth day in rats and after the ninth day in guinea pigs) decrease in wound collagen concentration has been noted.[5,8,9] Although the lysis of collagen during the lag phase affected only the narrow zone about the wound, the lysis noted later is evident throughout the biochemically active zone of the wound; in the guinea-pig musculofascial wall it was seen as far as 7.4 millimeters from the wound proper. Also, the balance between collagen synthesis and lysis is more homogeneous, resulting in a wider reactive zone in which the collagen concentration and collagen orientation are more even throughout the zone and there is maximum tensile strength per unit area. In scorbutic guinea pigs collagen lysis was much more marked and more prolonged. The lowest wound collagen was measured five days after wounding and only by the fifteenth day had the wound regained the collagen concentration of normal tissue.[8]

Recently Grillo and Gross demonstrated collagenolytic activity in the margins of open skin wounds in rats from 48 hours after wounding until the wound was healed.[16] Both epithelial and mesenchymal elements were required. However, in our studies collagen lysis was clearly observed in musculofascial wounds where epithelial elements could not participate. This is not easily explained, but the mechanisms of collagen lysis may be considerably different in sutured and open wounds.

Lack of Healing and Wound Disruption

A slight decrease in tensile strength of sutured wounds during the lag phase has been observed by Fast, Nelson, and Dennis[17] and by us.[8] This decrease parallels the collagenolytic activity of the wound. Excessive collagen lysis may be one of the factors responsible for decreased strength in sutured

Continued

---

*See Test Your Word Score Page 1639.

wounds or even for frank wound disruptions. It is our opinion that *lack of healing* and *wound disruption* may be due to different and unrelated processes. *Lack of healing* means absence of collagen synthesis, whereas decreased tensile strength in a wound is a result of the lack of collagen synthesis and the increase of collagen lysis. In some situations collagen synthesis may be adequate; but the new collagen may be so actively lysed that none is present, leaving the wound without strength. Also, the reverse is true. In truly scorbutic animals there was no collagen synthesis in sutured incisions for a period of 15 days;[8] however, none of these wounds disrupted. We believe that the explanation for this is the near absence of collagen lysis in the wounds, leaving the old established collagen fibers undisturbed. With the sutures in place these wounds could hold; however, when they were tested after removal of the sutures there was absolutely no breaking (tensile) strength. We believe that in some clinical situations collagen synthesis proceeds normally but is outstripped by a very active collagen lysis which then destroys old and new collagen, leaving the wound markedly deficient in collagen and susceptible to wound disruption.

Summary

Collagen synthesis is the ultimate achievement of the chemical changes occurring in a wound and is responsible for the wound's strength. From many sources, evidence is now being presented to suggest that lysis of collagen is widely encountered and is an essential aspect of normal wound healing. A balance between collagen synthesis and collagen lysis must be achieved. When defective healing is encountered, the balance has been disturbed: there is either insufficient synthesis or excessive lysis. Finally, the spectrum of collagen chemistry in open wounds may be vastly different from that observed in closed, sutured wounds.

Experitissimum

Experitissimum was Gilbert of England's magical formula for treating epilepsy in the thirteenth century: At the first access of the disease, when the patient falls to the ground, all his clothes except his shirt should be removed and placed at his feet. The nails of all his fingers and toes should next be clipped and wrapped in a cloth. A long white thorn is then to be split and the patient dragged feet first through the cleft as far as his middle. The thorn should then be cut into bits and placed with the nail parings. Next the patient's hair should be cut in three places. These clippings of hair and the knife used in the operation are then to be added to the other paraphernalia wrapped in the cloth, and the whole is to be buried underground, and the following words uttered. In the patient's right ear, "Christ conquers"; in his left ear, "Christ reigns"; and to his face, "Christ commands."

Lynn Thorndike in A History of Magic and Experimental Science.

Abstracts, Briefs and Commentaries

EXTENSION-FLEXION NECK STRAIN

"Whiplash" is not a good term, as there is no seven-pound weight on the end of a whip. The injury has been noted for thousands of years. The present cause of most of these injuries is a rear-end auto collision, with the recipient in a relaxed position.

The term "whiplash" indicates ligamentous injury in an area where ligaments are many and intricate. Bony injuries and ligamentous tears may be revealed by x-ray. Prolapsed discs have been diagnosed. The torn ligaments of the cervical spine are compared with those of a sprained ankle which may not heal well, leaving a relaxed joint. The symptoms due to trauma may be severe, resulting in headache, paresthesia, muscle spasm, and pain.

The majority of the injuries involve the lower cervical spine. High spinal involvement may cause subluxation with referred pain along the occipital nerves. Prolapsed discs have been reported in 26 per cent of patients with cervical sprain; but this is not the experience of the authors. Vague symptoms of blurring vision, diplopia, vertigo, nausea, etc. have been attributed to injuries to such structures as the vertebral arteries and to the vascular supply to the cord.

Initial treatment consists of adequate immobilization of the neck by a cast or Peterson brace. Hospitalization may be advisable. Traction is not recommended. Heat, relaxants, and sedation may be indicated. Immobilization of the neck is instituted for at least six weeks. Many patients continue to have symptoms after removal of the brace and require further treatment, such as steroid injections of trigger points. However, the authors believe that 80 per cent of patients lose their symptoms within one year.

From 1956 to 1963 more than 10,000 patients with neck pain were seen at the Mayo Clinic. This report is not concerned with patients operated upon for discs or fractures due to trauma involving the neck, but with 32 patients with cervical sprain that required fusion. These operations were determined by a history of severe trauma, persistent for one year or more; surgery was also resorted to in cases where symptoms, relieved by four weeks of immobilization, returned after removal of supports.

All 32 patients had severe accidents, 23 in rear-end collisions. An average

Continued

of 28.3 months elapsed between the accident and the operation. The trial brace relieved the pain and showed the patient what he might expect from surgery. All 32 patients had recurrence of symptoms after the trial immobilization.

Surgical treatment consisted of fusion of the lower cervical and upper thoracic vertebrae by bone grafts. Marked mobility of the spinous processes, laceration of some of the interspinous ligaments, with calcium deposits and tissue degeneration, were found at surgery.

Postoperative results are divided into four groups based on signs and symptoms. Among 31 patients followed none were the same or worse than before surgery; 64.5 per cent had excellent results; 25.8 per cent good results; and 9.7 per cent only fair results.

The authors also discuss the history, causes, and prevention of neck injuries.

Comments: This report is most interesting and timely, as it deals with a field often lucrative to the malingerer and his attorney, and a pain in the neck to the physician. Whether true or false, subjective symptoms are hard to classify. The authors note that some patients get relief when their claims are settled, as was the case in the so-called "railway spine." The review is excellent and based on extensive personal experience.

FOOD ALLERGY

The diagnosis of food allergy should be reached by using one or more diagnostic procedures, since no single method is totally accurate. First, one should try to establish the existence of food allergy in the patient; and second, one should attempt to identify a specific food as a cause of symptoms. If skin tests are used, they should be employed in the light of their limited value. They are never to be used alone, but should be supplemented in every instance by other diagnostic measures. Diets are featured by the omission of one or more of the most common allergens. When the patient is freed of symptoms, then the individual foods are checked in order to make the specific diagnosis. The deliberate feeding test, which is slow but highly accurate, requires the absolute cooperation of the patient in eliminating the food to be tested for four days. Only one food can be tested each day, which makes the diagnosis a prolonged procedure. In light of present knowledge, the provocative food test seemed safe, comparable in accuracy to the feeding test, with the advantage of making possible several tests in one day. Statistically, the authors have analyzed the time of reaction, the common neutralizing dilutions, and the comparative value of the deliberate feeding test.

VENOGRAPHY OF LOWER EXTREMITIES

One hundred and six venograms of the lower extremities were performed in 77 patients. Venography was employed to aid in diagnosis in clinically equivocal thrombophlebitis to diagnose previous disease of the deep veins, to evaluate thrombolytic therapy, and to study the natural history of thrombophlebitis. Thirty patients were examined because of suspected thrombophlebitis, but the diagnosis was radiographically confirmed in only two. Of nine patients with a history of previous phlebitis or with unexplained swelling, deep venous obstruction was present in only two. In 27 patients in whom serial venograms were made to evaluate fibrinolytic therapy, some lysis was observed in 9. The examination is easy to perform and complications are minor and infrequent. Venography of the lower extremity is a valuable adjunct in the examination of the deep veins of the lower extremity, because the deep veins are often difficult to evaluate clinically, and bedside examination is often inconclusive or misleading.

ALCOHOL-PANCREATIC DUCT

Clinical evidence indicates that alcohol is important in the pathogenesis* of pancreatitis. Researchers suggest several ways in which the alcohol works: 1, it acts directly on the cells of the pancreas through the blood stream; 2, duodenal congestion produces obstruction of the ducts; or 3, persistent vomiting causes regurgitation of duodenal contents into the ducts. Acute pancreatitis has frequently been observed to follow overindulgence in food or alcohol. The mechanism was thought to be rupture of the smaller ducts due to increased pancreatic duct resistance. Hemorrhagic pancreatitis has been produced in dogs by the intravenous injection of secretin after ligation of the ducts.

The authors studied several procedures after the main-duct catherization to accurately record intraductal pressures. Intravenous injection of secretin produced a prompt rise in intraductal pressure associated with active construction of the pancreatic duct papilla. Morphine injected intravenously produced a rise of intraductal pressure about twice that of secretin. Intravenous alcohol produced no elevation of pressure; but duodenal instillation of 20 cc. of 10 per cent alcohol increased the pressure to about half that of secretin. The instillation of 20 cc. of 20 per cent alcohol into the duodenum produced a similar response which lasted about twice as long.

The investigators concluded that secretin, morphine, and alcohol increased intraductal pressure, but that alcohol was effective only when introduced into the duodenum.

Comments:

A patient of ours who was unaccustomed to the use of alcoholic drinks had an attack of pancreatitis following a moderate amount of wine, and one year later he had a similar attack after drinking wine at a family anniversary. Following the second attack we performed a plastic operation on the ampulla with no subsequent reported recurrence.

STRABISMUS IN GENERAL PRACTICE

Great confusion reigns among the medical profession as to when a cross-eyed child should be referred to an ophthalmologist. This should be between six and nine months of age because visual and muscular coordinated reflexes, resulting in normal vision in each eye and in stereopsis, are developed at six months of age, and 80% are fixed by the age of two. Thus normal anatomic relations shortly after six months of age are necessary to avoid the formation of fixed, irreversible, abnormal reflexes leading to amblyopia and lack of stereopsis. It is emphasized that the insidious divergent strabismus must be treated in infancy in spite of apparent temporary improvement. It is suggested that among the reasons for delay in referring strabismus cases is the receipt of incorrect advice from the family doctor or from optometrists.

EMOTIONAL PROBLEMS IN THE ADOPTEE

Comparisons were made between emotionally disturbed adoptees and emotionally disturbed non-adoptees in child and adult populations. Diagnostic categories were similar, but there were significantly higher percentages of aggressive and sexual behavior in the adopted child and of alcoholism and sexual behavior in the adopted adult groups. These symptoms appeared despite the fact that in over 60% of the subjects adoption had taken place prior to their sixth month of life. The greatest percentage of the group was reported as having no reactions to first being told of their adoption. Fantasies were reported about natural parents, leading in a number of instances to an active searching for them.

CORRECTIVE NASAL SURGERY IN CHILDREN

Obstructive nasal and septal deformities in children are usually traumatic and involve the cartilaginous septum and especially the caudal end of the septum. Surgical correction is required to avoid secondary facial deformities associated with chronic mouth breathing. Surgical treatment is conservative and is limited to previously injured tissues. The septum is transfixed and freed bilaterally. Pedicle grafts are formed from the deviated cartilage with minimal removal. Minor deformities of the external nose may also be corrected. The long term results demonstrate retention of the restored nasal airway and satisfactory development of the external nose.

CADAVER TRANSFUSIONS

Following the Russian lead, the authors show that cadaver blood can be successfully transfused from a suitable donor body, dead less than six hours, directly into a living recipient via a sterile rubber tube, using either a syringe and three-way stopcock or a simple closed pressure recipient tubing set with filter. They suggest the use of this method in battalion or regimental aid stations, field hospitals, base hospitals, or even in a foxhole on the battlefield itself. The dead man would simply be laid close to the soldier in shock and the transfusion proceeded with. Cross matches are not necessary. The surgeon or corpsman need take only a fleeting moment to check blood types listed on "dog tags" and proceed accordingly.

SPONTANEOUS PNEUMOTHORAX

A review of 213 spontaneous pneumothoraces in 170 patients, over a 12-year period, is presented. Conservative treatment, thoracentesis, tube drainage, and pleural scarification are compared as to time, success of re-expansion, and complications of the treatment. Re-expansion was obtained in 54% of 92 pneumos with 26 days in hospital (no complications); in 38% of 103 pneumos treated with thoracentesis, 13 days in hospital (no complications); in 74% of 95 pneumos treated with tube drainage, 11 days in hospital (6 complications, 1 death attributable to treatment); and in 98% of 46 pneumos treated by major thoracotomy (43 with pleural scarification) and with 15 days in hospital (2 complications, 1 death). The authors' present policy of management of spontaneous pneumothorax includes: conservative management of cases with less than 10-15% collapse; initial thoracentesis in those with more than 15% collapse; tube drainage if thoracentesis does not hold the re-expansion obtained; in tension pneumothorax, tube drainage of those not immediately responding to thoracentesis; pleural scarification, usually with blebectomy, in those not expanded within 10 days with tube drainage, and in recurrent pneumothorax.

STEROIDS IN HEPATITIS

The comparative effect of long-term steroid therapy on both hepatic function and pathologic changes was studied in a case of active chronic hepatitis. Steroids were withheld for short intervals during the period of study to determine the permanency of their effects and for purposes of control. The findings indicate that improvement in clinical well-being and in the results of biochemical tests may take place in the face of progression of the disease, as revealed in serial needle specimens of the liver. The observations leave open to serious question the effect of steroid therapy on the actual disease process of chronic hepatitis.

CLUBBING OF FINGERS

Clubbing of the digits, an unexplained sign associated with lung cancer, is diagnosed only if an altered angle between the nail and the finger exists.

Continued

The underlying process may progress to hypertrophic osteoarthropathy, with involvement of the periosteum and long bones. Clubbing associated with intrathoracic disease is best explained by a reflex increase of digital blood flow which originates in the thorax and is mediated through the vagus. Section of the vagus nerve can result in regression. Clubbing associated with extrathoracic disease remains unexplained, along with the observed changes in hormonal secretion, rouleaux formation in the blood, and the opening of peripheral and pulmonary vascular shunts. Multiple theories proposed previously are discussed, and caution is advised against the hasty acceptance of newer ones; the recent attempts to disassociate clubbing related to intrathoracic disease from hypertrophic osteoarthropathy remain premature.

DREAMS

Psychodynamic investigation was made of 2 subjects' dreams experimentally obtained but not told to psychiatrist by the subjects in subsequent interview. Subject A reported to the experimenter dreaming on 34 of 46 awakenings, 7 being reported to therapist. Subject B reported to the experimenter dreaming on 54 of 60 awakenings of which 41 were reported to the therapist who explicitly asked for dreams. Dreams containing attitudes which the dreamer anticipates will bring forth negative response from the psychiatrist are not recalled. For men these were strong homosexual feelings. For women this was initially guilty sexuality and later on intense denial of dependency. Four additional factors influence the process of dream reports to the psychiatrist: (1) being awakened and immediately telling the dream; (2) interest of psychiatrist in dreams; (3) relationship between patient and psychiatrist at the time of the interview; (4) time of night of dreams, later dreams being better remembered than earlier dreams.

Announcing

EUTRON™

pargyline hydrochloride 25 mg. and methyclothiazide 5 mg.

for control of
moderate to severe
hypertension

Unique combination produces greater antihypertensive effect with lower doses

Eutron is the combination in a single tablet of 25 mg. Eutonyl (pargyline hydrochloride) and 5 mg. Enduron (methyclothiazide). This combination produces greater therapeutic effect than that of either component used alone. Side effects may be milder, too, as dosages are generally lower. The effective dosage is usually one tablet, once daily. Tablets are scored for greater dosage flexibility.

Filmtab®
EUTONYL™
25 mg PARGYLINE HYDRO CHLORIDE
Caution Federal (U.S.A.) law prohibits dispensing without prescription
100 No. 6812
Tablets (Grooved)
ENDURON™
METHYCLO-THIAZIDE
Caution Federal (U.S.A.) law prohibits dispensing without prescription

Each Eutron tablet contains two proven antihypertensives in the ratio shown to be most effective in most patients.

TM—TRADEMARK

New EUTRON extends your range of treatment in moderate to severe hypertension

A single product you can use even in the presence of congestive heart failure or edema

Eight out of 10 patients respond

In clinical trials, Eutron produced normotension or a significant reduction in blood pressure in eight out of 10 patients studied. The rationale for the product is this: Eutonyl used alone is a potent antihypertensive. Its antihypertensive action is markedly enhanced by Enduron, a potassium-sparing thiazide.[1,2,3] The combination (Eutron) thus produces greater antihypertensive effect with lower dosages of the Eutonyl component, and milder side effects may be seen.

BP reductions in the recumbent and sitting positions often are nearly as great as in the standing. In clinical trials, the average *recumbent* BP reduction was 36/18 mm. Hg.

The average *standing* reduction in clinical trials was 45/22 mm. Hg. Thus the difference between the standing and recumbent readings was only 9/4 mm. Hg.

Significantly lowers blood pressure in all body positions; less likelihood of orthostatic hypotension

In clinical trials, the average reduction in standing blood pressure was 45/22 mm. Hg.; in the sitting position it was 48/20 mm. Hg.; and in the recumbent position, 36/18 mm. Hg.

Because Eutron effectively reduces blood pressure in all body positions, there is reduced likelihood of orthostatic symptoms or hypotension.

This was reflected in the relatively mild character of side effects seen in clinical trials (see below).

Smooth and gradual onset

Onset of antihypertensive action is usually quite smooth. Initial reduction of systolic and diastolic readings is usually seen within a week – maximum reduction in seven to ten days.

Less troublesome side effects may be seen; frequent improvement in "sense of well-being"

Fewer than 1% of patients studied discontinued Eutron therapy because of side effects. This is due in part to the relatively low dosage needed with the combination. Usual recommended dose is one tablet daily–that is, 25 mg. Eutonyl with 5 mg. Enduron. *This is about half the usual therapeutic dose of Eutonyl given alone.* As a consequence side effects may be milder. And, as with Eutonyl given alone, the patient may well note an increased sense of well being. This is in distinct contrast to most other antihypertensive therapy.

ABBOTT

Prescribing information for **EUTRON**

INDICATIONS: Eutron (pargyline hydrochloride and methyclothiazide) is indicated in the treatment of patients with moderate to severe hypertension, especially those with severe diastolic hypertension. It is not recommended for use in patients with mild or labile hypertension amenable to therapy with sedatives and/or thiazide diuretics alone.

CONTRAINDICATIONS: Eutron is contraindicated in patients with pheochromocytoma, advanced renal disease, paranoid schizophrenia and hyperthyroidism. Until further experience is gained it cannot be recommended for use in patients with malignant hypertension, children (under 12 years of age), or pregnant patients.

The concomitant use of the following is contraindicated: other monoamine oxidase inhibitors; parenteral forms of reserpine or guanethidine; sympathomimetic drugs; foods high in tyramine such as cheese; imipramine and amitriptyline, or similar antidepressants; methyldopa. A drug-free interval of two weeks should separate therapy and use of these agents.

WARNINGS: Pargyline hydrochloride is a monoamine oxidase inhibitor. Patients should be warned against eating cheese, and using alcohol, proprietary drugs or other medication without the knowledge of the physician. When it is necessary to administer alcohol, narcotics (notably meperidine), antihistamines, anesthetics, barbiturates and other hypnotics, sedatives, tranquilizers, or caffeine, these agents can be used cautiously at a dosage of ¼ to ⅕ the usual amount. Avoid parenteral administration where possible. Withdraw pargyline two weeks before elective surgery.

Patients should be warned about the possibility of postural orthostatic hypotension. Those with angina or other evidence of coronary disease should not increase physical activity. Pargyline may lower blood sugar. Potassium depletion is unlikely at the recommended dosage, but if it occurs, adjust dosage or withdraw or provide added natural food sources of potassium; potassium tablets should be avoided wherever possible, as bleeding or obstructive ulceration of the small bowel has been associated with their use; potassium levels should be especially watched if the patient is on digitalis or steroids, or if hepatic coma is impending.

PRECAUTIONS: When determining the antihypertensive effect of Eutron, blood pressure should be measured while the patient is *standing*. Use with caution in hyperactive or hyperexcitable persons. Such persons may show increased restlessness and agitation. Withdraw drug during acute febrile illness. Watch patients with impaired renal function for increasing drug effects or elevation of BUN and other evidence of progressive renal failure; withdraw drug if such alterations persist and progress. Pargyline has not been shown to cause damage to body organs or systems. As with all new drugs, complete blood counts, urinalyses, and liver function tests should be performed periodically. The drug should be used with caution in patients with liver dysfunction. With prolonged therapy, examine patients for change in color perception, visual fields, and fundi.

Elevated blood urea nitrogen, serum uric acid or blood sugar are possibilities attributable to the methyclothiazide in Eutron. Methyclothiazide may also reduce arterial response to pressor amines. Blood dyscrasias, including thrombocytopemia with purpura, agranulocytosis and aplastic anemia, have been seen with thiazide drugs.

SIDE EFFECTS: The use of pargyline may be associated with orthostatic hypotension. Mild constipation, slight edema, dry mouth, sweating, increased appetite, arthralgia, nausea and vomiting, headache, insomnia, difficulty in micturition, nightmares, impotence, delayed ejaculation, rash, and purpura have been encountered with pargyline. Hyperexcitability, increased neuromuscular activity (muscle twitching) and other extra-pyramidal symptoms have been reported. Drug fever is extremely rare. Congestive heart failure has been reported in a few patients with reduced cardiac reserve. Nocturia has been observed with the combination. If side effects persist, despite symptomatic therapy or reduction of the dose, discontinue the drug.

Book Reviews

Retirement without the love of letters is a living burial. — Seneca

HANDBOOK OF CLINICAL AND LABORATORY DATA AND PRACTICAL MANUAL FOR CLINICAL LABORATORY PROCEDURES (two volumes) — **First Edition. Editors: Henry C. Damm, Ph.D., and John King, M.D., Ph.D., The Chemical Rubber Co., Cleveland, Ohio, 1965. Price, $12.50 for single book, $22.50 for two.**

These companion volumes will serve as anchors for those who are being swept away by the tidal waves of the current medical literature. Using the format of *Handbook of Chemistry and Physics*, the editors bring together laboratory information in concise tables and brief discussions. Much of the data previously could be found only by foraging in dark corners of books and journals.

The board of editors, most of whom are associated with Western Reserve University or the Cleveland Clinic, have chosen contributors from both university and community hospitals. The result is a balanced, comprehensive presentation designed for physicians in active practice.

The material is wisely presented in two volumes. By not breaking the flow with interminable lists of methods, readability is achieved in the *Handbook* — a hardback compendium embracing most of clinical pathology. The material is introduced with early signs and symptoms of organ dysfunction, quickens with an appraisal of laboratory findings in related conditions, and culminates with a differential diagnosis.

The *Practical Manual*, on the other hand, is a looseleaf workbook with a straightforward "cookbook" presentation of methods. Included are procedures for blood banking, chemistry, hematology, histology, microbiology, and urinalyses. It will be a valuable source of lore for technologists and physicians who seek reliable, proven methods.

The uniqueness of the *Handbook* is its collection of useful data in an obtainable form. The pathologist can thumb to tables and discussions on such diverse but practical items as: dimensions and weights of organs in children and adults; proper handling and collection of bacterial specimens; automation, statistics, and quality control; toxicological techniques and absorption spectra of toxic compounds; and theories and procedures of immunohematology. The section on microbiology is refreshing — it has been shorn of oppressive minutiae. The clinician can fruitfully peruse "flow sheets" of endocrine function, assessments of acid-base balance, and a distilled critique of hematology.

My criticisms are minor and are counterbalanced by praise. The descriptions are scant, but the references are strategic. Some discussions, e.g., iron metabolism, are excessive, but this is compensated for by sinewy descriptions of other topics. The *Practical Manual* has neither a table of contents nor an index, but each section is separated by distinctive, easy-to-find colored pages — each with a list of contents of the section.

I recommend both volumes.

Richard L. Reece, M.D.
Minneapolis, Minnesota

OPHTHALMOLOGY PRINCIPLES AND CONCEPTS — **Frank W. Newell, C. V. Mosby Company, St. Louis, 1965. $12.25, 491 pages, 172 illustrations.**

This is a well prepared introduction to ophthalmology intended for the student. It would also serve well for the general practitioner or any other physician who wishes to have at hand a handy reference to the various ophthalmologic diseases. Bibliographical references are appended at the end of each chapter. For the specialist in ophthalmology the book would be didactic.

Carl O. Rice, M.D.
Minneapolis, Minnesota

MANAGEMENT OF THE PATIENT WITH SUBNORMAL VISION — **Gerald Fonda, M.D., F.A.C.S., C. V. Mosby Co., St. Louis, 1965. 161 pages, 88 figures, references, index, $11.00.**

This volume, written for the eye specialist, covers the application of various low visual aids to the needs of the partially sighted. The trend now is away from Braille and elaborate telescopic devices, which have been unjustly popularized, toward the use of strong convex lenses. These employ the principle of angular magnification in which regular print brought close to the eye is enlarged proportionally to the reduction in reading distance. In young persons the same effect can be obtained by using available accommodation which is not as commonly thought harmful. Of course, this does not improve distance vision and is not as useful in diseases characterized by marked reduction in visual field.

This book is well written, illustrated, and edited and fills a void in the literature.

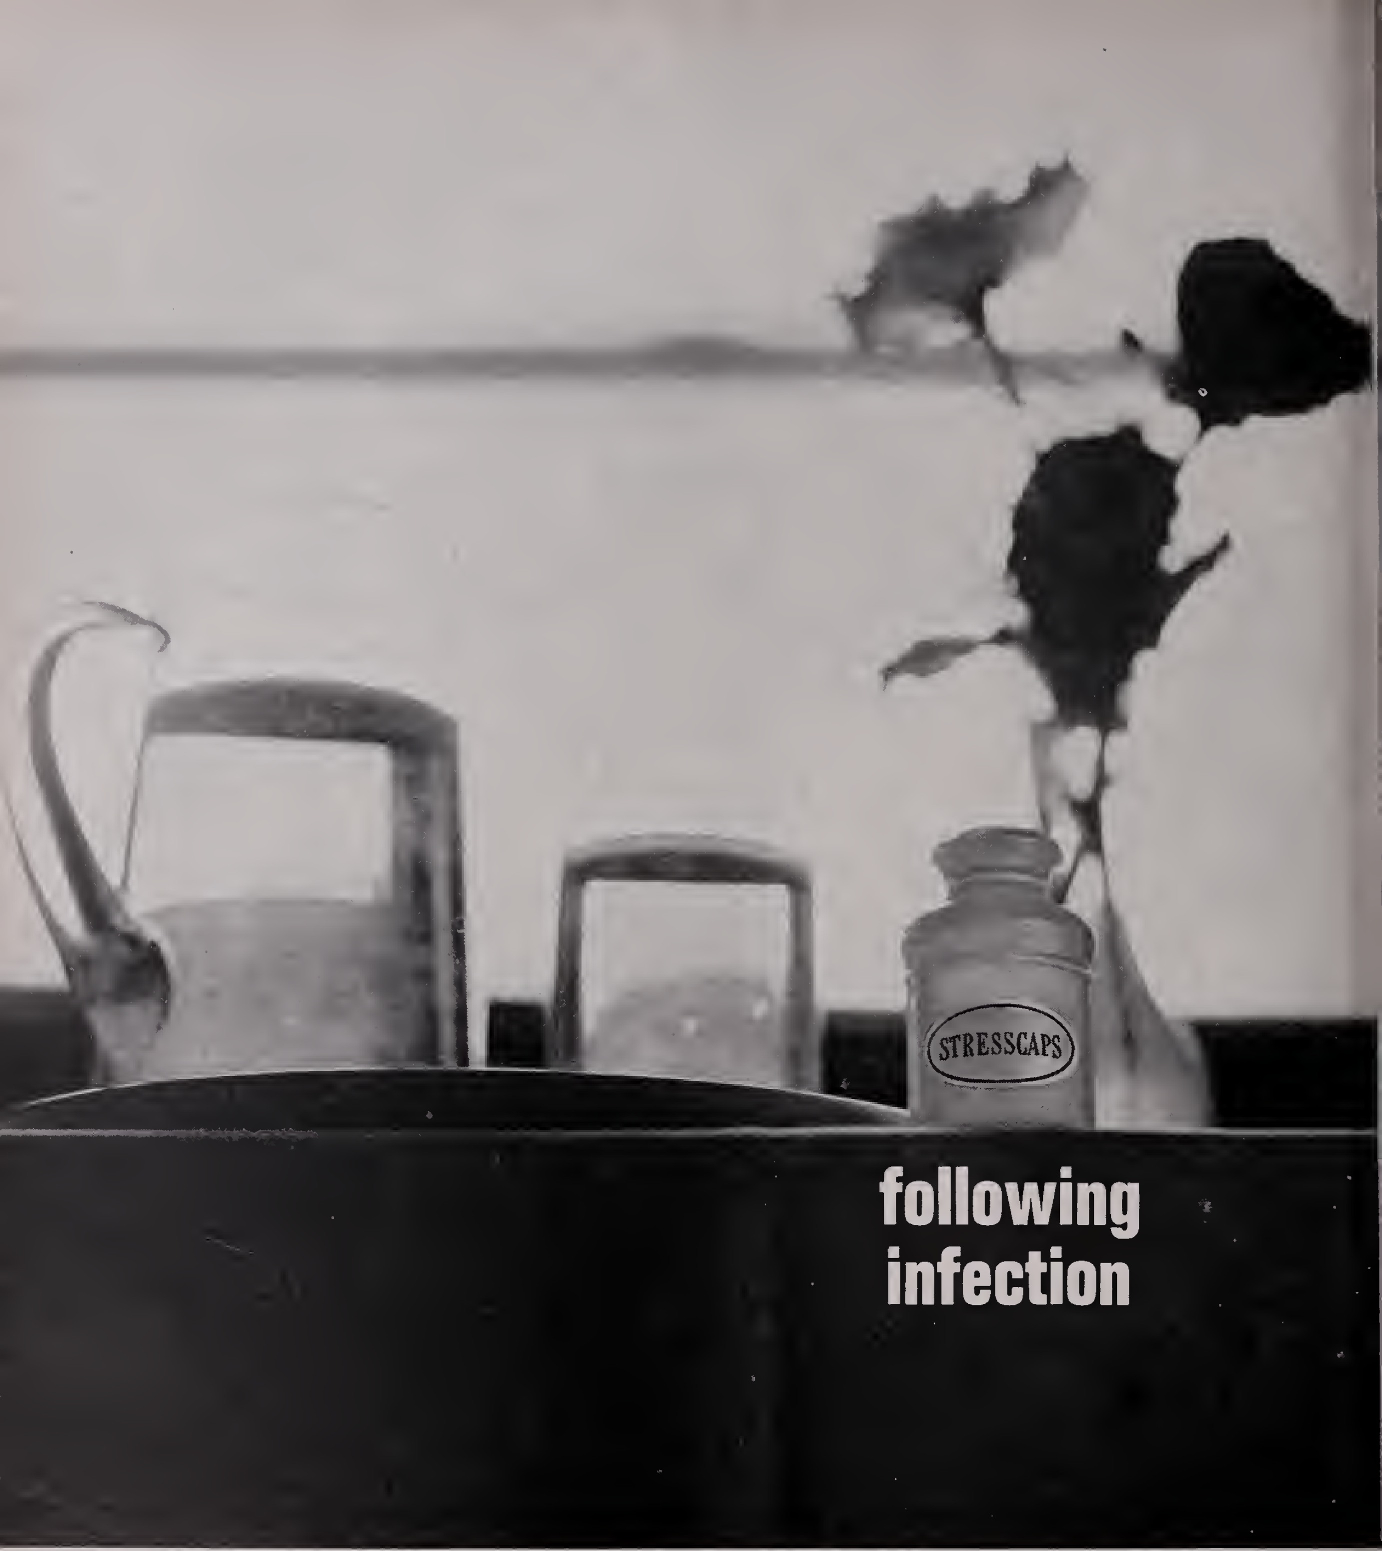
Minneapolis, Minnesota



STRESSCAPS B and C vitamins in therapeutic amounts...help the body mobilize defenses during convalescence...aid response to primary therapy. The patient with a severe infection, and many others undergoing physiologic stress, may benefit from STRESSCAPS.

STRESSCAPS®

FOR PROFESSIONAL RECOMMENDATION ONLY

Stress Formula Vitamins Lederle

Each capsule contains:

Vitamin B_1 (as Thiamine Mononitrate)	10 mg.
Vitamin B_2 (Riboflavin)	10 mg.
Niacinamide	100 mg.
Vitamin C (Ascorbic Acid)	300 mg.
Vitamin B_6 (Pyridoxine HCl)	2 mg.
Vitamin B_{12} Crystalline	4 mcgm.
Calcium Pantothenate	20 mg.

Recommended intake: Adults, 1 capsule daily, for the treatment of vitamin deficiencies. Supplied in decorative "reminder" jars of 30 (one month's supply) and 100 (three months' supply).

Some Reflections on Births and Infant Deaths among the Low Socioeconomic Groups*

EVELYN E. HARTMAN, M.D., M.S.**
ETHEL B. SAYLES, B.S.†
Minneapolis, Minnesota

MINNEAPOLIS AND environs constitute a medical center with a university medical school and hospital, a tax-supported county hospital, and nine private hospitals located within the City and three in outlying Hennepin County, all with maternity services. The number of private practicing physicians in Hennepin County is about 1,150, with a ratio of one physician per 730 population. The State ratio is one private practicing physician per 920 population. (Approximately 3,800 practicing physicians.)‡

The 1959 median family income in Minneapolis at $6,401 was well above both State and National figures (Table 1). The live birth rate in Minneapolis for 1961 and 1962, the resident live births in hospitals and the total number of live births to Minneapolis residents are also detailed in Table 1.

The prematurity and the illegitimacy rate are about the same as the national rate but above the State rate as illustrated in Table 2. Several social agencies located within the City provide care to unwed pregnant girls, attracting these girls to the City; this may account for the higher illegitimacy rate in Minneapolis.

The maternal, infant and fetal (20 weeks or more gestation) death rates in the City are about the same as State rates but considerably below national rates. The maternal deaths in the City from the medical standpoint are at an almost irreducible minimum. The only resident maternal death that occurred in 1962 was due to complications following abortion, either spontaneous or induced (unknown). The Minneapolis rates for perinatal mortality, which include fetal deaths at 20 weeks or longer gestation and neonatal deaths under 28 days of age, are about the same as the State rates, but well below the National rates.

From these statistics it would seem that the medical and hospital resources in Minneapolis are adequate and well utilized and that

Continued

the City is a safe place for expectant mothers to be delivered of their infants.

We were interested in determining whether or not these favorable rates were uniform throughout the City. If this was not the case, we wished to identify the problem areas and bring this information to the attention of responsible community groups, so that through the joint action of physicians, hospitals, and health and governmental agencies possible solutions to any problems of maternity care might be discussed.

Material

This study is based on collection and analysis of data from birth and infant death records for Minneapolis residents by census tracts; on social, economic and demographic characteristics of census tracts in Minneapolis according to the 1960 census; and on maternity patients at Minneapolis General Hospital in 1962. Included in this paper are:

1. Information on census tracts in Minneapolis with the lowest family income, lowest education, and highest unemployment, illustrated by maps.
2. Information on census tracts in Minneapolis with the highest birth, fertility, illegitimacy, prematurity, and infant death rates; with maps illustrating the areas in the City with the highest incidence of infant deaths and prematurity.
3. Comparison of the low socioeconomic areas in the City with areas having the highest birth, fertility, illegitimacy, prematurity and infant death rates.
4. Information on prenatal care for medically indigent patients attending the Minneapolis General Hospital in 1962.
5. Implications for community action.

Findings

Social, Economic and Demographic Characteristics

The median family income in Minneapolis (as shown in Table 1) is higher than in Minnesota and the United States. However, this is not uniform throughout the City,

TABLE I
Natality, Mortality and Income
United States, Minnesota, Minneapolis

with 13.9 per cent of families having an income under $3,000. The social, economic and demographic characteristics of census tracts, including median family income, white versus nonwhite population, median years of school completed, male unemployment, and median value of owner-occupied housing in Minneapolis according to the 1960 census vary considerably. Maps 1 and 2 show the census tracts in the City with the lowest family income, the lowest educational attainment, and the highest unemployment.

Although census tract 42 is not included on the 1960 map showing low family income, because public housing redevelopment was not completed in this area until 1962, a recent survey by the Minneapolis Youth Development Project has shown that the average family income at $3,700 places it very close to the bottom of the range.

Births, Infant Deaths, Illegitimate Births, Premature Births and Fertility

Table 2 lists in descending order the top ten per cent of Minneapolis census tracts for live births, infant deaths, illegitimate births, premature births and fertility in 1961.

Map 3 shows the census tracts in the City falling in the top ten per cent for infant mortality and prematurity in 1961. Census tracts 39, 43, 69, 95, and 107 are in the top ten per cent for both infant deaths and prematurity.

Census tracts 43 and 69 are in the top ten per cent for prematurity and infant deaths, as well as for illegitimacy.

Low Socioeconomic Census Tracts vs. Tracts Having Highest Rates for Natality and Infant Mortality

Census tracts 34, 42, 10 and 73 are in the top ten percentile for live births, illegitimate births and fertility. Public Housing Developments for low income families are in census tracts 34 and 42. Census tracts 10 and 73 are tracts having low education and high unemployment, and low income and education respectively. Although none of these census tracts is included in the top ten per cent for infant deaths and prematurity, in two of them the infant death rate was higher than the City rate of 23.9 and in three the percentage of premature live births was higher than the City-wide percentage of 7.0. The infant death rate for census tract 42 (for 1962) was 11.1 and the percentage of premature live births, 7.8. The infant death rates for census tracts 34, 10 and 73 (1961) were 46.4, 0.0, and 26.0 respectively; and 7.22, 5.05 and 9.09 per cent for prematurity.

Census tracts 39, 43 and 69 which were in the top ten percentile for infant deaths and

premature births are also low for economic conditions. Infant deaths alone were high in the low socioeconomic tracts of 41, 48, 52, 62, and 70; and prematurity alone was high in the low socioeconomic tracts of 29, 35, 37, 46B, 47, and 58.

Infant deaths and prematurity in combination or separately were also high in the following census tracts in which the socioeconomic conditions were slightly lower than for the City as a whole: 9, 27, 104; and in the following census tracts in which the socioeconomic conditions were the same or higher than in the City as a whole: 95, 107, 118 and 120A.

Prenatal Care

About 10 per cent of Minneapolis births in 1962 occurred at Minneapolis General Hospital,* which is a resource for outpatient and hospital care for medically indigent patients meeting financial and residency eligibility standards, and for emergency care. In 1962 a total of 1,308 women delivered at the hospital. Of these, about 43 per cent had no prenatal care or made only one visit to the prenatal clinic. Of women attending the hospital prenatal clinic, about 3 per cent made their initial visit in the first trimester, 26 per cent in the second, and 71 per cent in their last trimester. Of the 1,032 women who delivered at the hospital and had made one or more visits to the prenatal clinic, seven had stillbirths. Of the 276 who delivered and had no prenatal care, 11 had stillbirths.

Evaluation of Findings

Our findings would indicate that medical and hospital resources in Minneapolis are adequate for those who can afford and are motivated to use them. Prematurity, maternal, infant and perinatal mortality rates in the City compare very favorably with State and/or National rates. These favorable rates, however, do not apply evenly to all parts of the City.

We find that generally the census tracts with low socioeconomic conditions have a high incidence of prematurity and infant deaths, and of live births, illegitimacy and fertility. There are, however, some exceptions. Prematurity and infant deaths for instance are high in four census tracts in which the socioeconomic level is the same or higher than for the City as a whole. Another notable exception is census tract 42, which includes two public housing developments and is close to the bottom for average family income. This tract is high for live births, illegitimacy and fertility, but extremely low for infant deaths and only slightly higher than City average for prematurity. We have no explanation for this and can only speculate. Illegitimacy is high in this tract and many families are on ADC. Are mothers who are receiving public assistance for their children more apt to seek medical care for themselves and their children through welfare programs? Are the Minneapolis Health Department well-child clinics and public health nurses providing good preventive services to the infants and motivating mothers to get prenatal care?

Lack of Prenatal Care

Information on prenatal care for medically indigent patients delivered at Minneapolis General Hospital in 1962 shows that about 43 per cent of the expectant mothers had no prenatal care or made only one visit to the prenatal clinic. Seventy-one per cent of those who attended prenatal clinic made their initial visit in the last trimester. Of mothers having no prenatal care 4 per cent had fetal deaths, which is considerably higher than the 0.7 per cent of fetal deaths for mothers who made one or more visits to the prenatal clinic. These findings pose some questions:

1. Does lack of prenatal care contribute to prematurity, perinatal mortality and other handicapping conditions in the infant which may become financial burdens for the community?

2. Do eligibility standards for residency restrict the use of existing facilities by medically indigent patients for prenatal care?

3. Is lack of motivation on the part of the patients a primary reason for not getting adequate prenatal care?

Studies have shown that there is a relationship between lack of prenatal care and

a high incidence of prematurity and perinatal deaths.[1-3] The impact of the factor of prematurity upon neonatal mortality[4] and other perinatal casualties, including cerebral palsy,[5] has been reported. The relationship between low socioeconomic conditions and lack of prenatal care has further been stated by a WHO[6] report.

For the 276 patients who delivered at Minneapolis General Hospital in 1962 and had no prenatal care, lack of eligibility for care may have been the reason. In order to qualify for care other than emergency care, patients must meet both financial and residency requirements. For patients who made their first visit to the hospital prenatal clinic in the last trimester of pregnancy, lack of motivation for various reasons may have been the prime factor.

Obstacles to Adequate Prenatal Care[7]

1. Lack of transportation. Prenatal clinics in Minneapolis are held at General Hospital and University of Minnesota Hospitals for those eligible for care. Some private hospitals have at various times conducted prenatal clinics admitting medically indigent patients who were good teaching cases. No clinics are held in outlying neighborhoods close to the population groups needing prenatal care.

2. Problem of finding a baby sitter for other children in the family during the mother's absence.

3. Poor understanding of the need for prenatal care. Patients are probably aware of the fact that maternal deaths are rare, but lack awareness of the preventive aspects of good care to the infant. The additional advantage of mental-health support to the expectant parent through adequate prenatal care may not be recognized.

Meeting the Needs of the Indigent

Possible solutions toward meeting the needs of these medically indigent maternity patients and their infants would be: (1) set up neighborhood prenatal clinics to serve population groups that find it difficult to travel to a distant hospital clinic; (2) waive residency eligibility restrictions and admission based on arbitrary stage of gestation; (3) initiate a public health education program to motivate all expectant parents to seek early prenatal care, with special understanding of the needs and cultural differences of the economically and socially deprived; (4) intensify the public health nursing program in the low socioeconomic areas of the City to mothers and children; and (5) make provision for hospital care for high-risk maternity patients and their infants before "emergency" care is necessary.

Summary

With a few exceptions, the census tracts with low socioeconomic conditions generally had a high incidence of prematurity and infant deaths, and of live births, illegitimacy and fertility. Seventy-one per cent of expectant mothers who attended Minneapolis General Hospital Prenatal Clinic made their first visit in the last trimester of pregnancy. Of mothers who had no prenatal care, 4 per cent had fetal deaths as compared to 0.7 per cent of fetal deaths for those who had made one or more visits to the Prenatal Clinic.

Reports in literature have shown that there is a relationship between lack of prenatal care and high incidence of prematurity and perinatal deaths on the one hand; and a relationship between prematurity and neonatal mortality and other perinatal casualties on the other hand. Obstacles to adequate prenatal care have been listed.

History of Medicine

The Tradition of Austin Flint and Alexander Skene at "Long Island"

It is a welcome privilege to prepare for MINNESOTA MEDICINE an historical introduction to the contributions of the clinical departments of the State University of New York Downstate Medical Center.

Being a descendent of Minnesota pioneers, and a Carleton graduate, as well as former Dean of the Long Island College of Medicine, and its successor in the State University, makes the task doubly enjoyable.

The selection of such outstanding figures as Austin Flint and Alexander J. C. Skene as the ones who established the great clinical tradition at the "Long Island" is inevitable, for they were of the stature to cast shadows of inspiration far into the future. Symbolic of their enduring fame is that their names are known to every student of medicine today.

Austin Flint, a graduate of Harvard Medical School in 1832, was a pupil of James Jackson, who was an enthusiastic admirer of Laennec. As a consequence, Flint became the outstanding exponent of the new approach to physical diagnosis, popularizing the use of the stethoscope, and gave his name to a previously undefined heart murmur. Samuel Gross of Philadelphia said of him, "I know of no one who is so well entitled as Austin Flint, Sr., to be regarded as the American Laennec." At Buffalo, Long Island, New York University, and New Orleans he was the great clinical teacher of his day.

He loved to work with medical students directly at the bedside and in the clinics.

At one of his characteristically scholarly lectures delivered at the beginning of his professorship at the Long Island College Hospital in September, 1860, his subject was the anemias. In discussing cases of Addisonian "idiopathic* anemia," he referred to the work of a previous investigator, a Dr. Handfield Jones, who had discovered by microscopic examination of stomachs of patients coming to autopsy that 75 out of 100 cases revealed more or less atrophy of the tubuli. Dr. Flint, in commenting on the importance of the gastric glands, could "see how fatal anemia must follow an amount of degenerative disease, reducing the amount of gastric juice so far that the assimilation of food is rendered wholly inadequate to the wants of the body." He went on to say, "I shall be ready to claim the merit of this idea when the difficult and laborious researches of someone have shown it to be correct."[1]

It was some 70 years before the "difficult and laborious researches" predicted by Austin Flint found the answer to the riddle.

Dr. William B. Castle, Francis Weld Peabody Faculty Professor of Medicine at Harvard, gave the answers in his reports, "Observations on the Etiology Relationships of Achylia Gastrica to Pernicious Anemia," in 1929, and "The Nature of Extrinsic Factor" in 1932. It was as Flint had predicted; the answer was in the gastric mucosa!

Continued

Alexander Johnson Chalmers Skene, after earlier studies in medicine at Toronto and Michigan, received his M.D. at Long Island College Hospital in 1863, just ten years after his idol, James Marion Sims, the creator of gynecology as a specialty, had arrived to begin his career in New York.

Skene, however, fell immediately under the influence of Austin Flint, Sr., his Professor of the Practice of Medicine and Pathology. Inevitably, his exposure to so brilliant and inspiring a teacher had a profound influence in shaping his life's work. Later it was recorded that "to no part of his professional life was he more fond of looking back than to that which he spent as an assistant to Austin Flint, Sr.," . . . from 1866 to 1867 . . . "he was proud of the skill which he then acquired in the diagnosis of cardiac and pulmonary diseases, and attributed much of his subsequent success in the treatment of his patients to his ability to recognize the existence of disordered conditions, other than those of the sexual organs, and to his appreciation of these conditions. Too often nowadays the specialist emerges fullgrown from the medical college, lacking oftentimes any general experience whatever in hospital or private practice. . . ."[2] How true today in 1965!

Skene's range of interests was broadened by his love of art, through which he became a fine amateur sculptor. A bust of J. Marion Sims, which he executed, is a treasured possession of the Medical Society of the County of Kings. He felt that this experience in sculpture was fine training for the eye and hand which could augment the skill of the surgeon.

Beginning as Assistant Professor of Obstetrics and Diseases of Women at the Long Island College Hospital in 1866, by 1870 he was Professor of Gynecology, then Dean of the Faculty, and President of the College until the end of his distinguished career.

Skene's literary contributions include associate editorships of such journals as the Archives of Medicine and the New York Gynecological and Obstetrical Journal; authorship of six books and 96 medical papers and published addresses. Since his heavy commitments to the demands of his teaching and practice filled his days, his writing was all done in the morning before breakfast!

His mechanical ingenuity caused him to devise numerous surgical instruments, the patterns of which are generally used today, without recognition of Skene's part in the invention of them. His well-known observation on the urethral glands in 1880, until that time the seat of intractable trouble, has made his name known today to every student of medicine.

One of Skene's many disciples was a kindred spirit, interested both in gynecology and the arts, Robert Latou Dickinson.

One day in the early 1880s, toward the end of a surgical clinic, Skene observed a student in the front row of the amphitheatre busily coloring a sketch he had made of the operative procedure just completed. Skene was so impressed with the artistry and fidelity of the picture that he engaged the student on the spot to illustrate his forthcoming text on gynecology!*

The student was **Robert Latou Dickinson**, whose art was so unique that it is worthy of a brief account. At the age of 10, in 1871, when he and his father were paddling a homemade canoe in the Adirondacks, he impulsively decided to dive into the river. What happened in Dickinson's own words was, "Just then a little eddy swung the canoe right under me. The stem was of galvanized iron with the top bent sharply so that the point was as keen as a knife. That's what I hit."

---

*A. J. C. Skene, Diseases of Women, D. Appleton & Co., New York (1888 and 1892).

As Dr. Dickinson later told me the rest of the story, he partially eviscerated himself through an eight-inch tear in his abdominal wall, and swam ashore holding his intestines back in one hand! Inasmuch as the village doctor was too crippled with arthritis to grasp a needle holder, the local cobbler placed the sutures of waxed thread under the doctor's guidance. After weeks of drainage and the escape of some sand and pebbles, the boy recovered! That experience led him into medicine!

During his convalescence his father took him to Europe, where he had his first art lessons with pencil and brush in Paris. Upon his return he entered the Long Island College Hospital where he was inspired by Skene and thereafter maintained a lifelong passion of dual devotion to gynecology and art (both sketching and sculpture). He was a pioneer in family planning and control of conception, long before the scare term "population explosion" had been coined.

In the 1920s, Dickinson made a tour of hospitals in the interior of China, Audubon-style sketching as he went. On his return, just before I went to China, he answered my inquiry of how to keep up medically in an isolated station as follows: "Select an unsolved problem each year, record your observations exactly and systematically, read everything published about it, and write up your conclusions for publication. If you do, you won't 'go to seed' professionally."

Dr. Edward C. Rosenow, Jr., Executive Director of the American College of Physicians, was then serving as an English teacher with Carleton-In-China, in Fenchow, Shansi, but with a strong medical interest, inspired by his Mayo Clinic father. Following the Dickinson formula, he had the enterprise to determine the blood groupings of 1000 local Chinese, and published his first medical article with me in the Chinese Medical Journal, as to the biochemical index. As an important by-product of that research, a 'walking blood bank' was established, and the first transfusions in China were given in that area.

The tradition of fine clinical teaching at the bedside, in the clinic, and in the amphitheatre, nurtured throughout the earlier years at Long Island College by such stars in the academic firmament as Flint, Skene, Dickinson, and many others, has been continued into more recent years by such figures as John Osborn Polak, Alfred Beck, Charles Gordon, and Louis Hellman — worthy followers of Skene!

Emil Goetsch, a disciple of William Halsted at Hopkins and of Harvey Cushing at the Peter Bent Brigham, became the master surgeon in dealing with thyroid conditions and the preceptor of a long line of finely-trained surgeons in his pioneer residency system, the third in the United States. The eminent neurosurgeon, E. Jefferson Browder, one of that galaxy of residents, and also a preceptee of Harvey Cushing, followed Dr. Goetsch. His successor, **Clarence Dennis,** is carrying on in the same tradition as Professor-in-Charge of a great system of surgical services, including the University Hospital, Kings County Hospital, and a group of affiliated institutions.

Other figures sustained the ideals of research and teaching, such as

Continued

Dr. George M. Sternberg, Director of the first privately endowed bacteriology laboratory in the United States; The Hoagland Laboratory of Long Island College; Dr. Jean Redmond Oliver, renowned figure in renal pathology; and the revered Dr. Frank L. Babbott, Jr., President of the College from 1931 to 1941. Dr. Babbott, himself a pediatric specialist highly trained at Yale and Johns Hopkins, was instrumental in bringing in Dr. Charles Weymuller as professor-in-charge to be followed in turn by full-time chairmen, first Dr. Richard Day and then the current chairman, Dr. Jonathan T. Lanman. Drs. Luther Warren and Tasker Howard, Professors of Medicine, were followed by the brilliant Dr. William Dock, who might be styled a present-day Austin Flint. Dr. Dock, the first full-time Professor of Medicine at Long Island College of Medicine, was succeeded by Dr. Perrin H. Long and then by the present Chief of the Department, Dr. Ludwig W. Eichna.

All these and many others played essential roles in the great transition, when the Long Island College of Medicine became the nucleus in the Downstate Medical Center of the State University of New York in 1950, which now, with tremendously strengthened and enhanced faculty, facilities, teaching, research, and patient care, rounds out 105 years of medical history.

Under the leadership of Dr. Robert A. Moore, present President and Dean of the State University Medical Center for New York City, there has been rapid growth over the past decade. To the new Medical Science Building, constructed before his arrival, there has been added a new University Teaching and Research Hospital, with outpatient clinic and residences for the student body. Also to the 2800-bed university-controlled services of Kings County Hospital there has been added an impressive array of affiliated hospitals, both private and public, under full-time leadership, which have been brought under the Center's teaching and research direction, providing immense resources for internship and residency training, and a vast program of postgraduate education for physicians and other health personnel. Other developments are a collegiate nursing school and a consolidated medical library center in cooperation with the Medical Society of the County of Kings, creating one of the great resources of medical literary reference in the country.

The papers to follow from the Downstate Medical Center's clinical services reveal the extent to which the tradition set by Austin Flint and Alexander Skene and their followers continues to live!

Jean Alonzo Curran, M.D., L.L.D.*
Brooklyn, New York

Drive Safely

A driver who has a few quick ones may have a few close ones, too.

Wall Street Journal

Medical Economics

A Brief Explanation . . .

Social Security for Physicians

If you are a self-employed doctor of medicine you are now covered by Social Security retroactive to January 1, 1965. Under the provisions of the Social Security Act of 1965, the self-employment earnings from your medical practice are subject to tax and you and your family are eligible for future social security benefits.

For the year 1965, earnings totalling $4800 will be subject to tax and the amount which you will be required to pay on or before April 15, 1966, will be $259.20. In 1966, the amount of taxable income will increase to $6600 and the tax payable will be $405.90.

It is important to note that these amounts do not include taxes which have previously been withheld from salaries and other compensations ordinarily subject to Employees Social Security tax. Withholding coverage and liability for taxes for interns and residents will not begin until January, 1966.

Physicians self-employment social security tax rates are scheduled for a progressive hike from now until 1987 as follows:

Year	Combined Tax Rate Per Cent	Maximum Earnings Subject to Tax	Maximum Tax
1965	5.4	$4,800	$259.20
1966	6.15	6,600	405.90
1967 and 1968	6.4	6,600	422.40
1969-1972	7.1	6,600	468.60
1973-1975	7.55	6,600	498.30
1976-1979	7.6	6,600	501.60
1980-1986	7.7	6,600	508.20
1987 and after	7.8	6,600	514.80

Physician Benefits are Varied

For You

Old-Age Insurance Benefits — payable when you reach age 65 (reduced benefits are payable as early as age 62), for months in which you are retired or do little or no work. Benefits are payable beginning with the month you reach age 72 even if you do not retire. Disability Insurance Benefits — payable if you become disabled before age 65.

Benefits begin for the 7th month of your disability.

For Your Family

When you are entitled to old-age or disability insurance benefits:

Wife's Benefits — to your wife at age 65 (reduced benefits are payable as early as age 62). Benefits are payable to divorced wives under certain circumstances.

Mother's Benefits — to your wife under age 62 if she has in her care an unmarried child under 18 entitled to benefits based on your earnings, or a child entitled to childhood disability benefits because of your earnings.

Child's Benefits — for your unmarried children under age 18; the payments can continue until age 22 if the child is attending school full time.

Childhood Disability Benefits — for your child over 18 if the child became disabled before reaching age 18 and has been disabled ever since.

In the Event of Your Death

Widow's Benefits — to your widow at age 62 (reduced benefits are payable as early as age 60). Benefits are also payable to surviving divorced wives under certain circumstances.

Mother's Benefits — payable to your widow under age 62 if she has in her care your child under 18 who is entitled to benefits, or your child 18 or over who is entitled to childhood disability benefits.

Child's Benefits — for your unmarried children under age 18; the payments can

Continued

continue from age 18 to age 22 if the child is attending school full time.

Childhood Disability Benefits — for your child if the child became disabled before reaching age 18 and has been disabled ever since.

Dependent Parent's Benefits — to your dependent mother or father (or both) from age 62 on, provided you were contributing one-half of your parent's support at the time of your death.

Lump-Sum Payment — in addition to any monthly benefits, a lump-sum death benefit, which may be from $132 to $255, is payable at your death.

Health Insurance at Age 65

The Health Insurance Program for the aged has two parts:

Hospital Insurance — to help pay the costs of hospital care and certain other medical services.

Medical Insurance — to help pay the costs of physicians' services and certain other medical services not covered by hospital insurance.

Both programs start July 1, 1966.

Everyone 65 or older who is eligible for cash social security benefits (including the wife of an insured person) is also eligible for protection under the hospital insurance plan.

Nearly everyone 65 or over is eligible to enroll for medical insurance. Those who enroll will pay a premium (initially $3 monthly) for the protection, and the Federal Government will pay an equal amount.

Credits for Benefits

If you are a self-employed physician, you get four quarters of credit for each year in which your net earnings from self-employment are $400 or more.

If you are an employee, you get one quarter of credit for each calendar quarter in which you are paid wages of $50 or more.

To be insured for disability benefits — you need credit for at least 5 years of work in the 10-year period ending when you become disabled.

To be insured for retirement and survivors benefits — in general, the amount of work you need depends on the year you reach age 65 (62 for women) or on the year of your death if you die before that age.

To determine the amount of work required to qualify for retirement and survivor's benefits consult the following table prepared by the Social Security Administration.

If you reach age 65 (62 for women) or die in —	You will not need credit for more than this much work —
1957 or earlier	1½ years
1958	1¾
1959	2
1960	2¼
1961	2½
1962	2¾
1963	3
1964	3¼
1965	3½
1966	3¾
1967	4
1968	4¼
1969	4½
1970	4¾
1971	5
1975	6
1979	7
1983	8
1987	9
1991 (or later)	10

No one needs credit for more than 10 years of work to be insured for retirement or survivors benefits. Survivors benefits may be payable to your children and their mother if you have social security credit for 1½ years' work out of the 3 years before your death.

Credits Allowed for Previous Work

If you have at sometime done work that was covered by Social Security you may already have Social Security for some work. Also, if you were in the military service of the United States between September 15, 1940, and December 31, 1956, you may get social security credit for your active duty (unless it is counted toward certain other Federal benefits). Military service after 1956 is covered by the law in the same way as other kinds of employment.

Amount of Benefits

The benefit amount is based upon your average earnings under Social Security. Thus being insured merely means you are eligible. It does not determine the amount of benefits payable to you or your family. The benefit amount depends on your average earnings under Social Security.

The following table gives examples of retirement benefits. Additional benefits payable to dependents are not included.

Complete Retirement Unnecessary

You don't have to retire completely to get benefits. But if you expect to work while getting benefits, it is important to know how your earnings may affect your social security payments, advises the Social Security Administration. While under age 72, your total earnings and the number of months you work are the two things which determine how much in benefits can be paid to you.

Total Earnings — if you earn no more than $1,500 for a year after 1965, you will get benefits for all months for which you are otherwise entitled.

If you work throughout the year and earn more than $1,500, $1 in benefits will be withheld for each $2 you earn between $1,500 and $2,700. For every $1 that you earn over $2,700, $1 in benefits will be withheld.

Contact your local Social Security office if you have questions about Social Security, if you need a Social Security account number card, or if you wish to apply for benefits.

Born In		Retire In

Fatty Tumours

The steatoma is an abnormal growth of fat, which varies according to the nature of its site. It is of a uniform colour, yielding to the touch; at first it is small, but in time it enlarges. Most of them have their greatest circumference at the base; rarely they are found with a narrow base and widening towards the summit.

The fatty tumour differs from the strumous in being softer to the touch; it differs from the atheroma or the meliceride in being solid and not pitting on digital pressure; it also is cured by operation.

In operating, the incision is made right across the summit of the tumour, and is either simple or myrtle-leaf shaped according to the tumour. The capsule is now boldly cut away, for in these cases we do not fear sinus-formation in connection with the sac, as in melicere tumours or atheromas, since here the fat does not fall out when cut into. And there is another thing to bear in mind, as has been pointed out regarding strumous glands: if the steatoma is merely attached, one secures it by stripping it at the sides and below and shelling it out, now with the fingers and now with the handle of the knife; but, if it be closely adherent, then it must be dissected out. Then, after removal, the lips are stitched up, with a view to union; otherwise the bottom of the wound may be drained, and treatment by suppuration promoted.

Aetius of Amida, Sixth Century A.D.

Better Service, Doctor?

I DON'T
FEEL
GOOD!

Yes, Blue Shield wants to serve Minnesota doctors even better than it has. But we need your help.

When reporting claims, list symptoms for diagnostic laboratory and x-ray services ONLY. We do not need symptoms for any other service.

And, there must be a *direct* connection between those symptoms and the tests.

Payment for incomplete reports might be delayed . . . or rejected. Help us help you!

In Memoriam

Death is the liberator of him whom freedom cannot release; the physician of him whom medicine cannot cure; the comforter of him whom time cannot console.
— Colton

Death cannot come untimely to him who is fit to die. — The less of this cold world the more of heaven, the briefer life, the earlier immortality. — Milman.

JULIUS J. HEIMARK, M.D.

Dr. Julius J. Heimark, 77, Fairmont physician for thirty years prior to his retirement five years ago, died September 24th, in Phoenix, Arizona, following a stroke. Dr. Heimark was one of the founders of the Fairmont Clinic and Hospital, now the Fairmont Community Hospital.

He was born in Clarkfield, Minnesota, and graduated from the University of Minnesota Medical School. During his lifetime, Dr. Heimark belonged to many medical and civic organizations.

He is survived by his wife, a daughter, and two sons, one of whom is Dr. John Heimark of Mankato.

JACK R. PIERCE, M.D.

Dr. Jack R. Pierce, 46, former Virginia physician, died July 4th, at Buffalo, New York General Hospital. He was born in Arcade, New York, and graduated from the University of Buffalo Medical School. He practiced in Virginia for seven years before moving to Bradford, Pennsylvania.

He is survived by his wife and six children.

DANIEL E. GREENE, M.D.

Dr. Daniel Edward Greene, 50, Warren physician, died September 2nd. He was born in Pharr, Texas, and received his medical degree at the University of Omaha.

During his youth, Dr. Greene excelled in many sports and at one time was offered a career in professional baseball, however, he chose the medical profession. He was a member of many civic groups and a member of the Red River Valley Medical Society, Minnesota State Medical Association, and American Medical Association.

He is survived by his wife, two daughters and a son.

LEONARD T. CARLSON, M.D.

Dr. Leonard T. Carlson, 61, Minneapolis physician, died October 19. He was on the staffs of North Memorial and Glenwood Hills Hospitals, and medical examiner for the Selective Service Board since 1941.

He was born in Minneapolis and received medical degree at the University of Minnesota. He was a member of the Hennepin County Medical Society, the Minnesota Medical Association, American Medical Association, and the American Academy of General Practice.

He is survived by his wife, a son and a daughter.

L. HAYNES FOWLER, M.D.

Dr. L. Haynes Fowler, 69, formerly of Minneapolis, died October 13, in Newport Beach, California. He was born in Binghamton, New York, and received his medical degree at the University of Minnesota.

Dr. Fowler was a Minneapolis surgeon for thirty-five years before his retirement. He was associated with University Hospital and the Northwestern Hospital, and a fellow of the American College of Surgeons. He was a member of the Hennepin County Medical Society, Minnesota State Medical Association, and the American Medical Association.

He is survived by his wife.

The Blue Shield

Blue Shield of Minnesota, the state's largest medical-surgical plan, has taken another step for its future growth.

Since 1961, it has already grown about 36 per cent financially.

In 1965, if present trends continue, Blue Shield will have a $2 million growth year — double that of 1964.

In July, to continue its progress, Blue Shield moved into its new state headquarters at 2344 Nicollet Avenue in Minneapolis — an office building of more than double the office space Blue Shield had at 2218 University Avenue.

Paradoxically, Blue Shield, in its colorful history, is both an "old timer" and a young company.

Now 18 years old, it is one of the younger business organizations in the state. Yet, when it was founded in 1947 by doctors of medicine in Minnesota, it was the first medical-surgical organization in the state. It is, despite its few years, the pioneer health care plan of its type in Minnesota.

In 1947 the organization had no competition and grew rapidly. Today, in the face of competition from several hundred insurance organizations within the state, and several thousand insurance organizations throughout the U. S., it has had a growth rate of $1 million per year for the past four years. In 1961, Blue Shield had total revenues of $10.8 million. At the end of 1964, revenues reached $14.7 million.

By the end of this year, with an anticipated $2 million growth, Blue Shield will be nearly a $17 million organization.

A significant portion of Blue Shield's growth came from the improvement of coverage for existing subscribers.

Under the direction of the Blue Shield Board of Directors, the organization since 1961 has produced better medical-surgical plans, new hospital coverage plans, major medical coverage as well as more inclusive senior citizen coverage.

In 1961, Blue Shield entered the hospital coverage field by developing a hospital "rider" to its medical-surgical contract. The hospital coverage plan has a wide range of coverages to meet the various cost levels throughout the state. Daily room allowance plans can be purchased from $10 to $25 a day, with coverages from 30 to 720 days in group contracts.

The following year, and on an experimental basis, Blue Shield introduced its M-Series plan. This plan, which has since become available to the general public, is based on a new medically developed "relative value index."

It offers "Paid-In-Full" features to people whose incomes are up to $7,500 a year.

Also, Blue Shield developed a $20,000 Major Medical Contract. Sold only with the basic Blue Shield medical-surgical coverage, Major Medical pays up to $20,000 after a $100 deductible and on an 80/20 co-insurance basis. Its cost today ranges up to 60¢ a month for an individual and up to $1.20 for a full family. It is sold only to groups of ten or more people.

Blue Shield, which had a medical-surgical senior citizen program since 1959, offered a new and wider health care program in 1964 to people over age 65. The plan offered not only medical-surgical care but 90 days of hospitalization for each illness each year, plus 60 days of nursing home care.

Late last year, Blue Shield began supplementing its direct sales force with an "agency broker" system outside the Twin Cities to supplement its regular sales force. Now nearly 40 agents in rural Minnesota are handling Blue Shield for local customers.

Also in 1964, in one of the first acts of its kind in Minnesota, the Saint Louis County Board approved a plan in which Blue Shield would administer a program of medical care for welfare patients. The program is planned to begin late in 1965.

The organization has also been active in an intensive management development program, which has resulted in some dramatic changes, including increased sophistication of operation and substantial corporate growth. This effort was enhanced by the recruiting of a few top executives from outside the company. From Minneapolis General Hospital, Blue Shield gained its new controller and from an insurance company in Wisconsin, came its new marketing director. Blue Shield also hired new actuaries as well as new advertising and public relations consultants.

For the past several years, Blue Shield has been undergoing a reorganization toward more of a marketing rather than a "product" oriented company.

The increased service has brought to Blue Shield new departments and increased personnel. In 1960, Blue Shield had 38 employees. Today, the plan has nearly 200 people, most of which are at the state headquarters in Minneapolis, The balance are representatives throughout the state or people attached to Blue Shield's Duluth office.

Thus, Blue Shield, the first organization in the medical-surgical field in Minnesota, is undergoing a new period of growth.

When you sow wild oats, you always get a bumper crop. — Herbert Prochnow

Photographic Contest

The Editors of MINNESOTA MEDICINE, in collaboration with the Doctors' Photographic Society of Minneapolis, take pleasure in announcing a monthly photographic contest. The contest is to promote an interest in photography in the medical profession. First prize each month will be publication in full color of the winning picture in MINNESOTA MEDICINE.

The following rules will govern the conduct of the contest:

1. Only doctors of medicine are eligible to submit pictures, and the picture must have been taken or composed by a physician.
2. Each contestant may submit not more than two pictures each month.
3. Only color transparencies, 35 mm. to 2¼", can be considered.
4. Each slide should be labeled with the maker's name, address, and the identifying title.
5. Slides should not be mounted on glass, but can be protected in plastic sleeves or envelopes.
6. Each entry must be accompanied by a self-addressed, stamped envelope if return of the picture is desired. Returns will be made shortly after the close of the contest each month. The winning photograph will be retained but will be returned after it has been used.
7. The deadline date for entry will be the 10th of each month and the winner of each month's contest will be announced in MINNESOTA MEDICINE in the subsequent issue. The date of publication will be three to six months in advance.
8. There will be no limitation on subject material except as indicated in item 10.
9. Model releases will be requested of winners where appropriate.
10. Judges will be selected by the editors of MINNESOTA MEDICINE and the Doctors' Photographic Society. The judges will be guided by the precepts of the Photographic Society of America, and winners will be based on appropriateness, interest, impact, and technical excellence.
11. The editors of MINNESOTA MEDICINE and the Doctors' Photographic Society cannot be responsible for entries lost or damaged, but every effeort will be made to protect submitted pictures.

Your pictures are hereby invited. Please submit pictures to:

Photo Contest Editor
MINNESOTA MEDICINE

WANTED: one or two general practitioners. Excellent clinic and hospital facilities. Rural practice established 18 years. Salary open, partnership if compatible. Lloyd H. Klefstad, M.D., Greenbush, Minnesota.

SACRED HEART, MINNESOTA, doctorless since 1961, wants general practitioner. Population 700, accredited hospital 10 miles away. Write: Rev. Robert Bardy, Phone 765-2547, Sacred Heart, Minnesota.

A THREE MAN group needs a fourth general practitioner in a fast-growing West St. Paul area. Begin with salary and join partnership with full participating advantages. Write: MINNESOTA MEDICINE — 326, 496 Lowry Medical Arts Building, St. Paul 55102.

GENERAL PRACTICE Minnetonka, 20 minutes from Minneapolis loop. Ideal location for solo start with expansion to clinic. New building. Hospital nearby. Good parking. Dentist now located in one wing. Call or write: Cliff Kommedahl, 12401 Minnetonka Blvd., Minnetonka, Phone 935-8247.

GENERAL PRACTITIONER WANTED: to associate with physician-surgeon in Owatonna, a Southern Minnesota community, 25,000 population. Clinic building three years old; with five large treatment rooms, lab.; x ray; central supply; two doctors' offices; pharmacy; and business offices. Located next door to 85 bed city hospital. Good opportunity for partnership. Contact: O. W. Roberts, M.D.; 920 South Cedar Street; Owatonna, Minnesota. Phone 451-4630.

LOCUM TENENS wanted for general practice in St. Paul from mid-February through March, 1966. Write: MINNESOTA MEDICINE — 328; 496 Lowry Medical Arts Building, St. Paul 55102.

MEDICAL ART. Drawings, charts and lettering for publication, slide lectures, movies, exhibits and television. Also three dimensional models. Al Hage — 339-1012, Minneapolis.

GENERAL PRACTITIONER AVAILABLE. Completing military June, 1966. Five years experience; married, desires group practice Rochester, Minneapolis, St. Paul or surrounding area, minimum OB and surgery. Write MINNESOTA MEDICINE — 331, 496 Lowry Medical Arts Building, St. Paul, Minnesota.

WANTED: young general practitioner to join six-man group consisting of 4 GPs, a general surgeon, and radiologist. College town of 5,500, 30 miles from Twin Cities. Also need LOCUM TENENS in general practice. Contact: Ed Jenkins, Mgr., River Falls Medical Clinic, River Falls, Wisc. Phone 425-5322.

WANTED locum tenens for month of February 1966. Can live in my home. If married, bring wife and children. Modern hospital and clinic, consultation available. Contact as soon as possible by mail or telephone: Wm. C. Heiam, M.D., Cook, Minnesota. Telephone: 666-3354 or 666-2261.

PHYSICIAN (General Medicine or Surgery) at 245 bed VA General Hospital in scenic Black Hills. Area offers excellent hunting, fishing, recreation. Requirements: Graduate approved school, citizenship, license any state, salary based on qualifications, housing available. Nondiscrimination in employment. Contact Chief of Staff, VA Center, Hot Springs, South Dakota 57747.

WANTED: Psychiatrist and general physician for full time staff positions in private psychiatric hospital currently in process of increasing range of inpatient and outpatient services. Midwest metropolitan area. Private practice opportunities after one year. Salary open according to qualifications. Attractive working conditions. Fringe benefits. Write: MINNESOTA MEDICINE — 333, 496 Lowry Medical Arts Building, St. Paul 55102.

WANTED SOMEONE in East Side St. Paul general practice who would desire temporary locum tenens, one, two or three months. Write: MINNESOTA MEDICINE — 335, 496 Lowry Medical Arts Building, St. Paul 55102.

WANTED: Generalist desiring fast start in too busy St. Paul practice. No covenants or contingent clauses. You move to available nearby independent office facilities as soon as you establish an adequate following of your own, or you stay as a partner if you desire. Incidentally lousy working conditions: new building, built-in Hi-fi, every third week off. If you desire to establish yourself permanently in present location. You name your own terms. Write MINNESOTA MEDICINE — 336, 496 Lowry Medical Arts Building, St. Paul 55102.

WANTED: Immediate opening for Young GP in an established medical corporation. Three man G.P. group located in rapid-growing North Suburban Metropolitan Area. 15 minutes from loop and large educational center. New clinic. New 150-bed hospital. Salary open, fringe benefits. Fridley Medical Center, P.A., 203 Mississippi Street, Minneapolis, Minnesota 560-2950.

THE FOLLOWING LABORATORY TESTS ARE AVAILABLE TO PRACTICING PHYSICIANS: *Fluorescent Anti-nuclear Antibodies (FANA):* A broad spectrum immunological method used in the diagnosis of autoimmune diseases. *Quantitative Latex Fixation for Rheumatoid Arthritis:* The titration of rheumatoid factor (s) in the diagnosis and follow-up of rheumatoid arthritis patients. *Anti-thyroglobulin Antibodies:* Used in the diagnosis of Hashimoto's thyroiditis. *Anti-mitochondrial Antibodies:* These are present in primary biliary cirrhosis cases. The test is used to differentiate this condition from surgical obstructive jaundice cases. *Macroglobulin Precipitin test:* This test is positive in Waldenström's macroglobulinemia and other related malignant conditions. *Protein Electrophoresis* in serum, urine, and spinal fluid. Fast one-day service. Mail *2 cc serum,* nonhemolized for one or more of the above tests. For more information write or call collect: Muharrem Gökcen, M.D., Ph.D., Research Laboratories, Glenwood Hills Hospitals, Minneapolis, Minnesota 55422, Phone: 612-588-9401. Booklets are available upon request.

FOUR STAFF ADDITIONS to Southern California Group of 24 physicians. Internist with chest subspecialty, ophthalmologist, otolaryngologist, general practitioner. Partnership possibility after first year. Administrator, Gallatin Medical Group, 10720 S. Paramount Blvd., Downey, Calif.

GENERAL PRACTITIONER — to join established group in progressive city of 15,000. Excellent clinic and hospital facilities. Salary open. For details contact: Richard Lehigh, Manager, Owatonna Clinic, 134 Southview, Owatonna, Minnesota 55060.

CLASSIFIED ADVERTISING

WANTED: Young internist and pediatrician, board certified or eligible, to join 6-man group consisting of 4 GP's, a general surgeon, and a radiologist. College town of 5,500 only 30 miles from Twin Cities. Salary open with early partnership opportunity. Write or call collect: Ed Jenkins, Mgr., River Falls Medical Clinic, River Falls, Wisc., phone 425-5322.

EXCELLENT and immediate opening for one or two physicians. 17 bed fully equipped municipal hospital with lab and x-ray facilities. Also private 40 bed nursing home. Complete clinic, including equipment, available for rent. Doctor owner retiring because of ill health. No investment needed. Prosperous agricultural community. Opportunity for rewarding lifetime practice. Phone 669-4421 collect, Clarkfield, Minnesota Hospital.

PSYCHIATRIC RESIDENCIES, positions available July 1966. Fully approved, balanced didactic and clinical experiences. Five-year career program: $8,895, $10,294, $12,048, $15,368, $16,203; NIMH general practitioner stipends $12,000 annually for three years in Michigan's water winter wonderland. Paul E. Kauffman, Ph.D., Director of Resident Training, Traverse City State Hospital, Traverse City, Michigan. An equal opportunity employer.

WANTED: General practitioner able to do surgery. Present physician wanting to "semi-retire." Good community, prosperous farming. Good schools and churches. New hospital and clinic buildings. Contact: Warren Clinic, P.O. Box 107, Warren, Minnesota 56762.

WANTED: Young G.P. for rural practice partnership. No initial investment. Previous partner and well equipped for dual practice. Good hospital — 12 miles and large medical center 30 miles on four lane highway. Small town in stable farming community, resort area, hunting and fishing, good school system. Contact: A. S. Mithune, M.D., Lake Park, Minnesota.

WANTED: Associate general practice. Minneapolis. No obstetrics. Excellent hospital affiliations. Postgraduate course available University Minnesota. Superb restaurants, Tyrone Guthrie Theatre, Symphony Orchestra. Unsurpassed boating, swimming, fishing. Prefer physician with service obligation completed. $18,000 first year; partnership thereafter. Write: A. L. Walonick, M.D.; 3015 Utah Avenue South, Minneapolis 55426

RELAXED, GRACIOUS COUNTRY LIVING viewing St. Croix River. Spacious, 3-bedroom, modern home on two acres — amidst stately shade trees. Recreation room. 17 miles to St. Paul. Write: Harlan Fisher, Route 5, Stillwater, Minnesota. Telephone 436-8844.

WANTED — Internist, board certified or qualified, to associate with two board certified internists. Ten man multi-specialty group. (Lenont Peterson Clinic, Virginia, Minnesota) — Heart of the expanding taconite industry.

FOR RENT: Successful medical building. Will help doctor or group of doctors get started in proven location in Northwest Suburban Minneapolis, 36th and Noble near two hospitals. Call or write Noble Drug, 4705 36th Avenue North, Minneapolis 22. Ju 8-9449.

DEPROL®

meprobamate 400 mg. +
benactyzine hydrochloride 1 mg.

Indications: 'Deprol' is useful in the management of depression, both acute (reactive) and chronic. It is particularly useful in the less severe depressions and where the depression is accompanied by anxiety, insomnia, agitation, or rumination. It is also useful for management of depression and associated anxiety accompanying or related to organic illnesses.

Contraindications: Benactyzine hydrochloride is contraindicated in glaucoma. Previous allergic or idiosyncratic reactions to meprobamate contraindicate subsequent use.

Precautions: *Meprobamate*—Careful supervision of dose and amounts prescribed is advised. Consider possibility of dependence, particularly in patients with history of drug or alcohol addiction; withdraw gradually after use for weeks or months at excessive dosage. Abrupt withdrawal may precipitate recurrence of preexisting symptoms, or withdrawal reactions including, rarely, epileptiform seizures. Should meprobamate cause drowsiness or visual disturbances, the dose should be reduced and operation of motor vehicles or machinery or other activity requiring alertness should be avoided if these symptoms are present. Effects of excessive alcohol may possibly be increased by meprobamate. Grand mal seizures may be precipitated in persons suffering from both grand and petit mal. Prescribe cautiously and in small quantities to patients with suicidal tendencies.

Side effects: Side effects associated with recommended doses of 'Deprol' have been infrequent and usually easily controlled. These have included drowsiness and occasional dizziness, headache, infrequent skin rash, dryness of mouth, gastrointestinal symptoms, paresthesias, rare instances of syncope, and one case each of severe nervousness, loss of power of concentration, and withdrawal reaction (status epilepticus) after sudden discontinuation of excessive dosage.

Benactyzine hydrochloride—Benactyzine hydrochloride, particularly in high dosage, may produce dizziness, thought-blocking, a sense of depersonalization, aggravation of anxiety or disturbance of sleep patterns, and a subjective feeling of muscle relaxation, as well as anticholinergic effects such as blurred vision, dryness of mouth, or failure of visual accommodation. Other reported side effects have included gastric distress, allergic response, ataxia, and euphoria.

Meprobamate—Drowsiness may occur and, rarely, ataxia, usually controlled by decreasing the dose. Allergic or idiosyncratic reactions are rare, generally developing after one to four doses. Mild reactions are characterized by an urticarial or erythematous, maculopapular rash. Acute nonthrombocytopenic purpura with peripheral edema and fever, transient leukopenia, and a single case of fatal bullous dermatitis after administration of meprobamate and prednisolone have been reported. More severe and very rare cases of hypersensitivity may produce fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (1 fatal case), anuria, anaphylaxis, stomatitis and proctitis. Treatment should be symptomatic in such cases, and the drug should not be reinstituted. Isolated cases of agranulocytosis, thrombocytopenic purpura, and a single fatal instance of aplastic anemia have been reported, but only when other drugs known to elicit these conditions were given concomitantly. Fast EEG activity has been reported, usually after excessive meprobamate dosage. Suicidal attempts may produce lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse.

Dosage: Usual starting dose, one tablet three or four times daily. May be increased gradually to six tablets daily and gradually reduced to maintenance levels upon establishment of relief. Doses above six tablets daily are not recommended even though higher doses have been used by some clinicians to control depression and in chronic psychotic patients.

Supplied: Light-pink, scored tablets, each containing meprobamate 400 mg. and benactyzine hydrochloride 1 mg.
Before prescribing, consult package circular.

ARCH LABORATORIES
A Division of Lewis-Howe Company
319 South 4th Street • St. Louis, Missouri 63102

Description: Hygroton, brand of chlorthalidone, is an oral diuretic agent of value in the treatment of edema and hypertension. The drug is notable for its prolonged action (48-72 hours) and low toxicity. It is not a thiazide and may often be employed successfully in patients who are intolerant of other agents or become refractory to them.
Indications: Hypertension and many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic disease.
Warning: With administration of enteric-coated potassium supplements, the possibility of small bowel lesions should be kept in mind.
Precautions: Reduce dosage of concomitant antihypertensive agents by at least one-half. Discontinue if the BUN rises or liver dysfunction is aggravated. Electrolyte imbalance and potassium depletion may occur; take special care in cirrhosis or severe ischemic heart disease, and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Side Effects: Agranulocytosis, constipation, dizziness, dysuria, headache, hyperglycemia, hyperuricemia, impotence, leukopenia, muscle cramps, nausea, postural hypotension, purpura, thrombocytopenia, transient myopia, urticaria, vomiting and weakness.
Average Dosage: One tablet (100 mg.) daily with breakfast.
Availability: Tablets of 100 mg. in bottles of 100 and 1000. For full details, see the complete prescribing information.

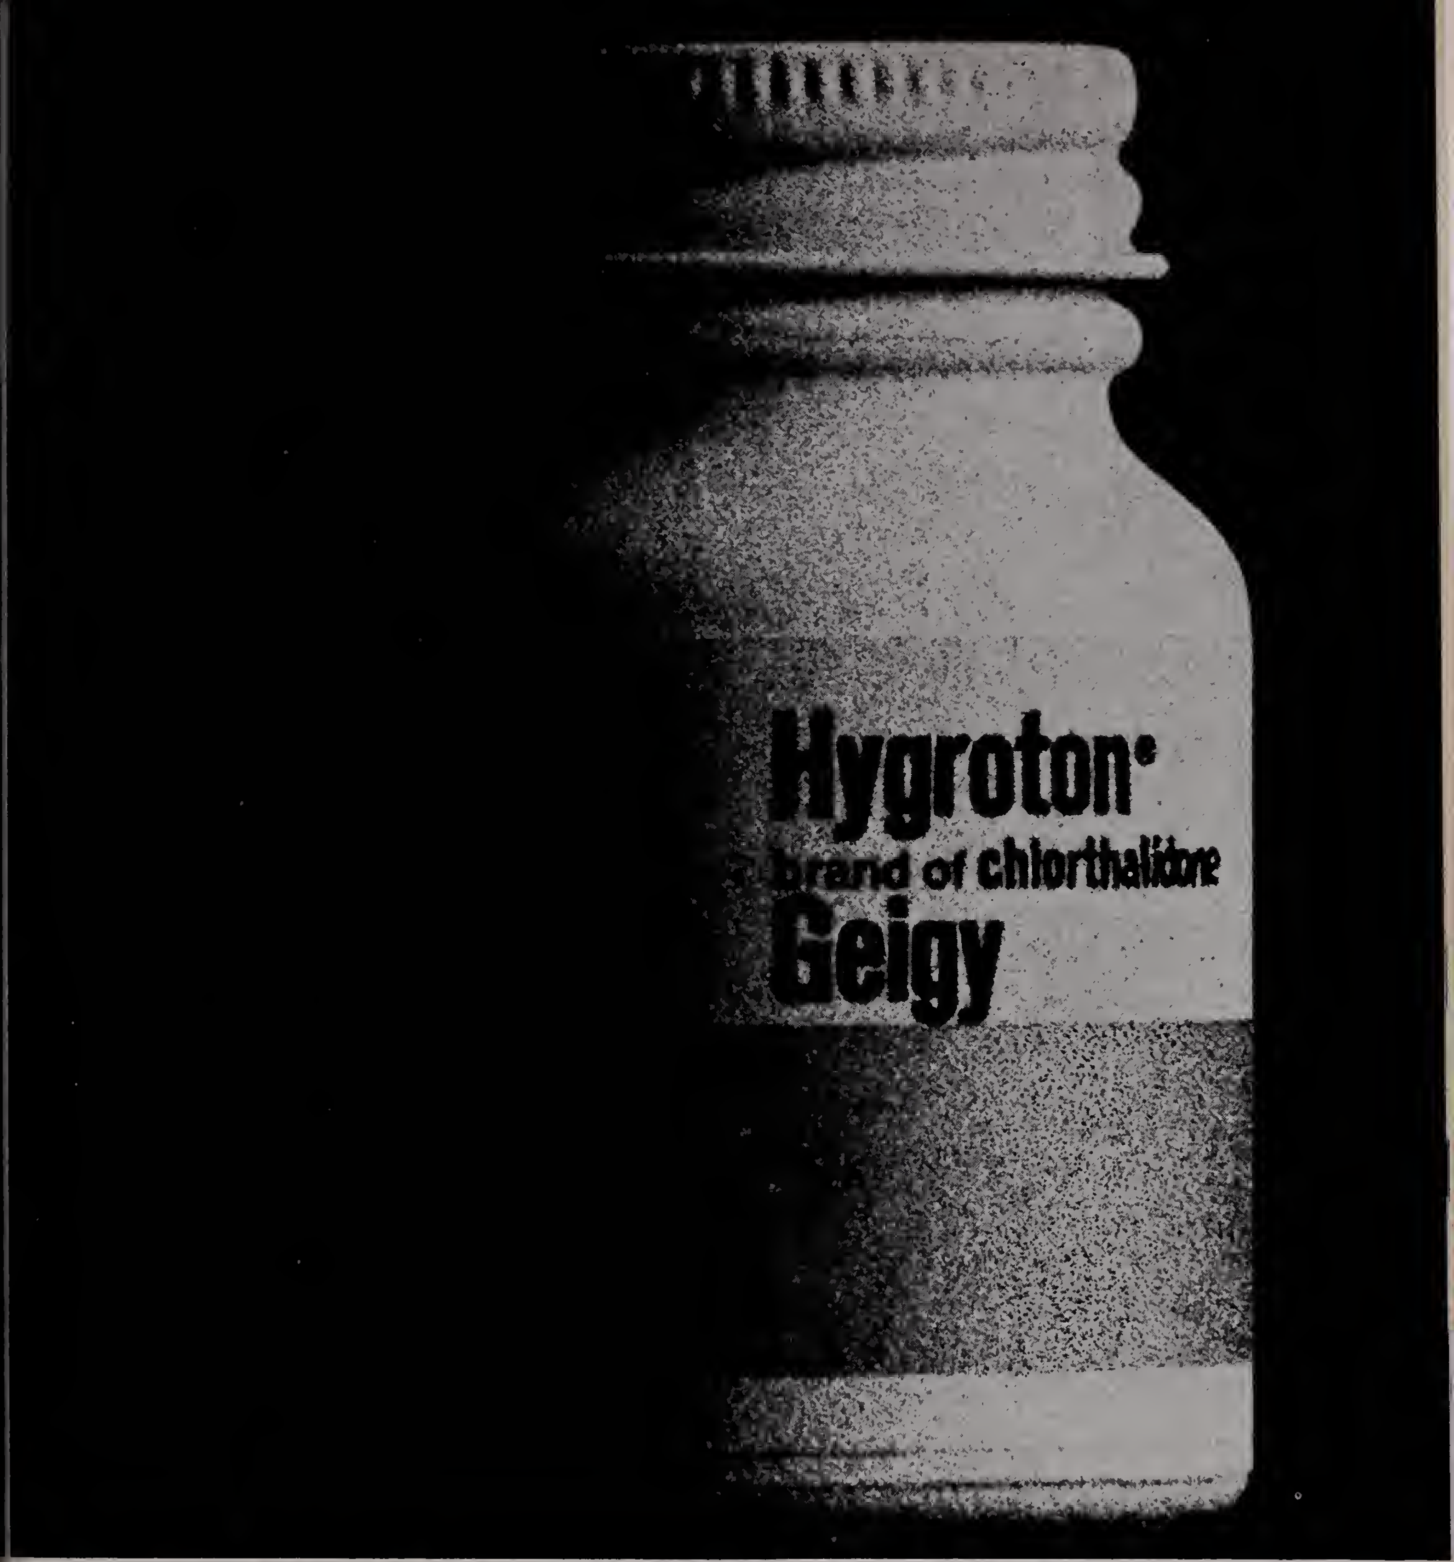
The long-acting diuretic

HY-3993 PC



vho needs it?

Patients with edema.
Edema in congestive heart failure.
Or in the premenstrual syndrome.
Edema in pregnancy...or obesity.
Patients you want to bring to dry weight.
And those you want to keep at dry weight.
Those you want on single daily doses.
And those requiring even fewer doses.
Those resistant to other therapy.
And those intolerant of other diuretics.
Those who have to pinch pennies.
And those who can afford the best.

too young
to be so tired...

revive interest...restore activity promptly with Alertonic®

Each 45 cc. (3 tablespoonfuls) contains: alcohol, 15%; pipradrol hydrochloride, 2 mg.; thiamine hydrochloride (vitamin B_1) (10 MDR*), 10 mg.; riboflavin (vitamin B_2) (4 MDR), 5 mg.; pyridoxine hydrochloride (vitamin B_6), 1 mg.; niacinamide (5 MDR), 50 mg.; choline†, 100 mg.; inositol†, 100 mg.; calcium glycerophosphate, 100 mg. (supplies 2% MDR for calcium and for phosphorus) and 1 mg. each of the following: cobalt (as chloride), manganese (as sulfate), magnesium (as acetate), zinc (as acetate), and molybdenum (as ammonium molybdate).

*Multiple of adult Minimum Daily Requirement supplied.
†The need for these substances in human nutrition has not been established.

the need for a tonic knows no age

Life *can* begin at forty—except when functional fatigue causes her to feel tired all the time; to start losing interest in friends and surroundings; to look and act older than her years. Alertonic—*a prescription tonic*—can help your patient become her normal self again. Alertonic helps relieve mild depression, revive interest and restore purposeful activity promptly...with a formula that is efficient *and* economical. Alertonic contains a mild central stimulant (pipradrol hydrochloride), 15% alcohol, essential vitamins and minerals. No hormones or MAO-inhibiting drugs are included. No iron. No iodine. One pleasant-tasting tablespoonful before each meal comprises the usual daily dose.

Indications: 1. Functional fatigue such as that often associated with: a depressing life experience or stressful time of life; advancing years; convalescence; limited activity or confinement. 2. Poor appetite and vitamin-mineral deficiency as they occur in: patients having faulty eating habits; geriatric patients who are losing interest in food; patients convalescing from debilitating illness or surgery.

Contraindications: As with other drugs with CNS-stimulating action, Alertonic is contraindicated in hyperactive, agitated or severely anxious patients and in chorea or obsessive-compulsive states.

Side Effects: Reports of overstimulation have been rare. Patients who are known to be unduly sensitive to the effects of stimulant drugs should be observed carefully in the initial stages of treatment.

Dosage: Adults, 1 tablespoonful; children (over 15 years old), 1 to 2 teaspoonfuls; children (4 to 15 years old), 1 teaspoonful. To be taken three times daily 30 minutes before meals.

THE WM. S. MERRELL COMPANY
Division of Richardson-Merrell Inc.

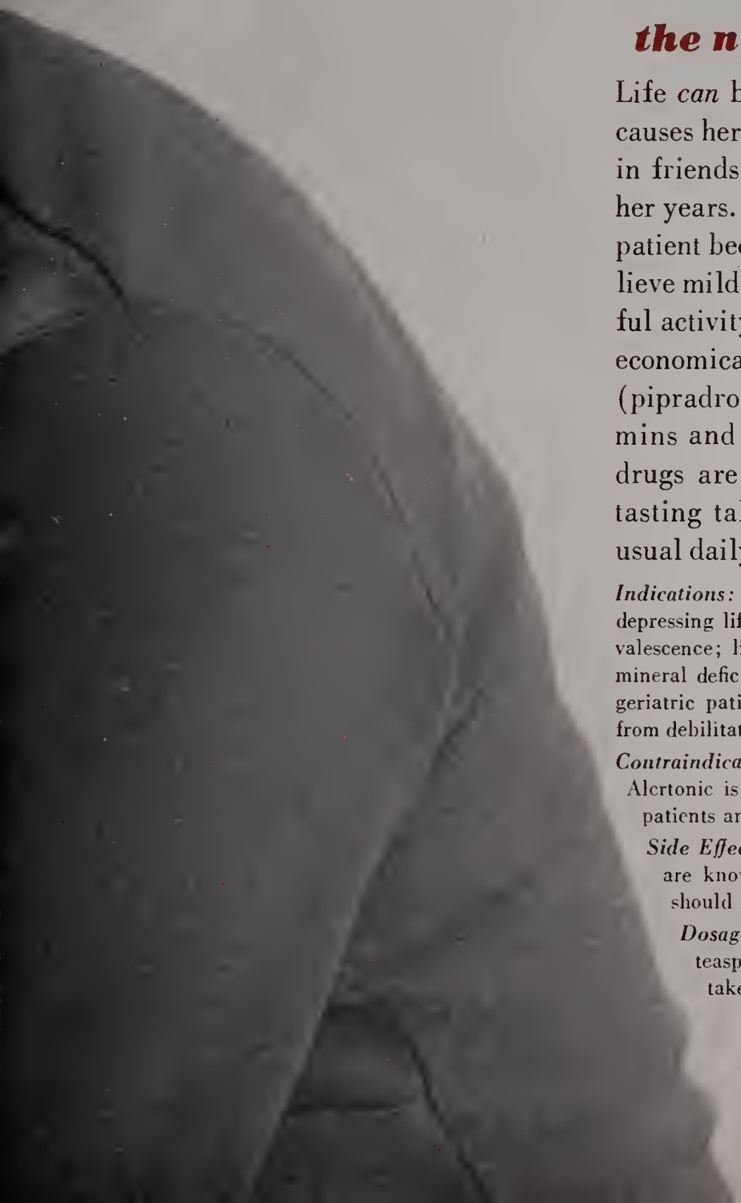
Merrell



When uncontrolled
diarrhea brings
a call for help

When the diarrhea sufferer has run the gamut of home remedies without success, pleasant-tasting CREMOMYCIN can answer the call for help. It can be counted on to consolidate fluid stools, soothe intestinal inflammation, inhibit enteric pathogens, and detoxify putrefactive materials—usually within a few hours.

CREMOMYCIN combines the bacteriostatic agents, succinylsulfathiazole and neomycin, with the adsorbent and protective demulcents, kaolin and pectin, for comprehensive control of diarrhea.

Indications: Diarrhea. *Contraindications:* Kaolin: Withhold if diverticulosis is present or suspected. *Precautions:* Sulfonamide: Continued use requires supplementary administration of thiamine and vita-

your ℞ for
Cremomycin
can provide relief

min K. Neomycin: Patient should be observed for new infections due to bacteria or fungi. *Side Effects:* Sulfonamide: Sensitivity reactions may occur (e.g., skin rashes, anemia, polyneuritis, fever; agranulocytosis with a fatal outcome has been reported). Reduction of thiamine output in the feces and of vitamin K synthesis has been observed. Neomycin: Nausea, loose stools possible.
Before prescribing or administering, read product circular with package or available on request.

promptly relieves diarrheal distress
Cremomycin®
ANTIDIARRHEAL

Composition: Each 30 cc. contains neomycin sulfate 300 mg. (equivalent to 210 mg. of neomycin base), succinylsulfathiazole 3.0 Gm., colloidal kaolin 3.0 Gm., pectin 0.27 Gm.

where today's theory is tomorrow's therapy

Minnesota Medicine at a Glance

Some Physiology on the Dumping Syndrome — Helft et al. Page 1601

Efforts to explain the cause of the dumping syndrome after a gastric resection have resulted in several theories, namely, the loss of circulating plasma into the intestine; the release of serotonin from the argentaffin cells of the duodenum; and a mechanical theory which suggests that there is distention of the jejunum and duodenum brought about by the introduction of hypertonic materials into the small intestine.

Helft and his co-workers performed some experiments on the animal using 50% glucose instilled into an iliac Thiry-Vella loop. They demonstrated that the concentrated glucose solution abolishes the ability of the iliac mucosa to absorb chlorides, inhibiting its ability to perform osmotic work, and that it also inhibits jejunal motility.

Pigskin Grafts — Bromberg and Song Page 1605

Though heterografts have never been found to be a permanent substitute for skin, recent studies have suggested that heterologous tissue be used as a temporary dressing for large skin defects resulting from burns.

Bromberg and Song have found pigskin to be more suitable for a variety of reasons, and they have observed that the graft is retained for an average of 18 days as against an average of nine days for animal grafts when these were used in animal experiments.

Cerebral Gigantism — Kowlessar Page 1610

The clinical observation of excessive growth in early childhood associated with mental retardation, clumsiness, hypothymism, high arched palate, and precocious sexual development suggests the immediate possibility of cerebral gigantism. Kowlessar provides the details in a case report of this unusual disease in which she found that there were quantitative abnormalities of adrenal hormone production considered to be secondary to the manifest central nervous system disorder.

Dialysis Therapy — Friedman Page 1615

Dialysis therapy is a substitute for the absent or diseased kidney in an effort to remove toxic materials from the blood stream which might otherwise be fatal to the individual.

Peritoneal dialysis as described by Dr. Friedman has been found to be effective in acute tubular necrosis and in prolonged aneuria which was potentially reversible. Although there are some complications associated with peritoneal dialysis, improved techniques and methods to conserve plasma protein will no doubt result in decreased morbidity and mortality.

Hemodialysis has been found effective particularly in drug intoxication.

Megaloblastic Anemia due to Folic Acid Deficiency — Robinson Page 1623

For the description of folic-acid deficiency and an associated megaloblastic anemia, the case report and studies done on this infant clearly delineate the differential features of folic acid and Vitamin B_{12} deficiency. Though the usual daily dose of folic acid has been considered to be from .4 to 10 mg., Robinson has clearly demonstrated that 50 micrograms of pteroylglutamic acid is sufficient to result in a complete cure for this infant's megaloblastic anemia, suggesting that the minimal requirement of folic acid is small.

Replantation of Limbs — Shaftan et al. Page 1645

There have been instances in which replantation of a limb has been successful. Under certain circumstances this procedure can be recommended, though there may be some question as to whether a functionless though viable limb provides enough benefit for a patient to subject himself to the ordeal that follows replantation.

Malignancy of the Female Genitalia — Nelson Page 1651

Carcinoma of the ovaries or an endometrial carcinoma does not respond well to radical pelvic surgery.

In carcinoma of the cervix there are some contraindications to radical surgery, but for the Stage I lesion radiation and radical hysterectomy have been found to be satisfactory, with a survival rate of from 75 to 90 per cent.

Rectal Bleeding — C.P.C. Page 1673

There are not many lesions which cause both rectal pain and bleeding. For evaluation of an interesting clinical path conference, the case history and physical findings can be profitably studied.

Hyperparathyroidism — Rosen et al. Page 1681

There are seven clinical manifestations of hyperparathyroidism but only two are commonly encountered. Renal calculus formations occur in about 70 per cent of the cases and gastrointestinal symptoms in 25 per cent.

The other five clinical manifestations of hyperparathyroidism and the criteria for establishing the diagnosis are detailed in the medical conference.

Lack of Wound Healing — Collagen Synthesis,
Enquist and Adamsons Page 1695

The lack of wound healing and wound disruption may be due to different and unrelated processes. The most important biochemical change occurring in a healing wound is the synthesis and orientation of collagen fibers by fibroblasts. This manuscript reviews the advances that have been made in the study of collagen synthesis which plays an important role in the early phases of wound healing.

It hurts more to have a belief pulled than to have a tooth pulled, and no intellectual novocain is available. — Elmer Davis

DEXTROSTIX-Apply this side

WHO NEEDS A BLOOD-GLUCOSE DETERMINATION?

Many of your patients, Doctor. With **DEXTROSTIX®** Reagent Strips, estimating blood glucose takes only 60 seconds. The test can be used for screening in every physical examination and emergency situation. **DEXTROSTIX** is also useful for checking blood glucose in pregnancy, obesity, peripheral vascular disease, certain endocrine disorders, patients on "thiazides" and other potentially hyperglycemic drugs, diabetic screening and management, and other conditions where hypo- or hyperglycemia may be of clinical significance. ☐ Ames Company, Inc., Elkhart, Indiana

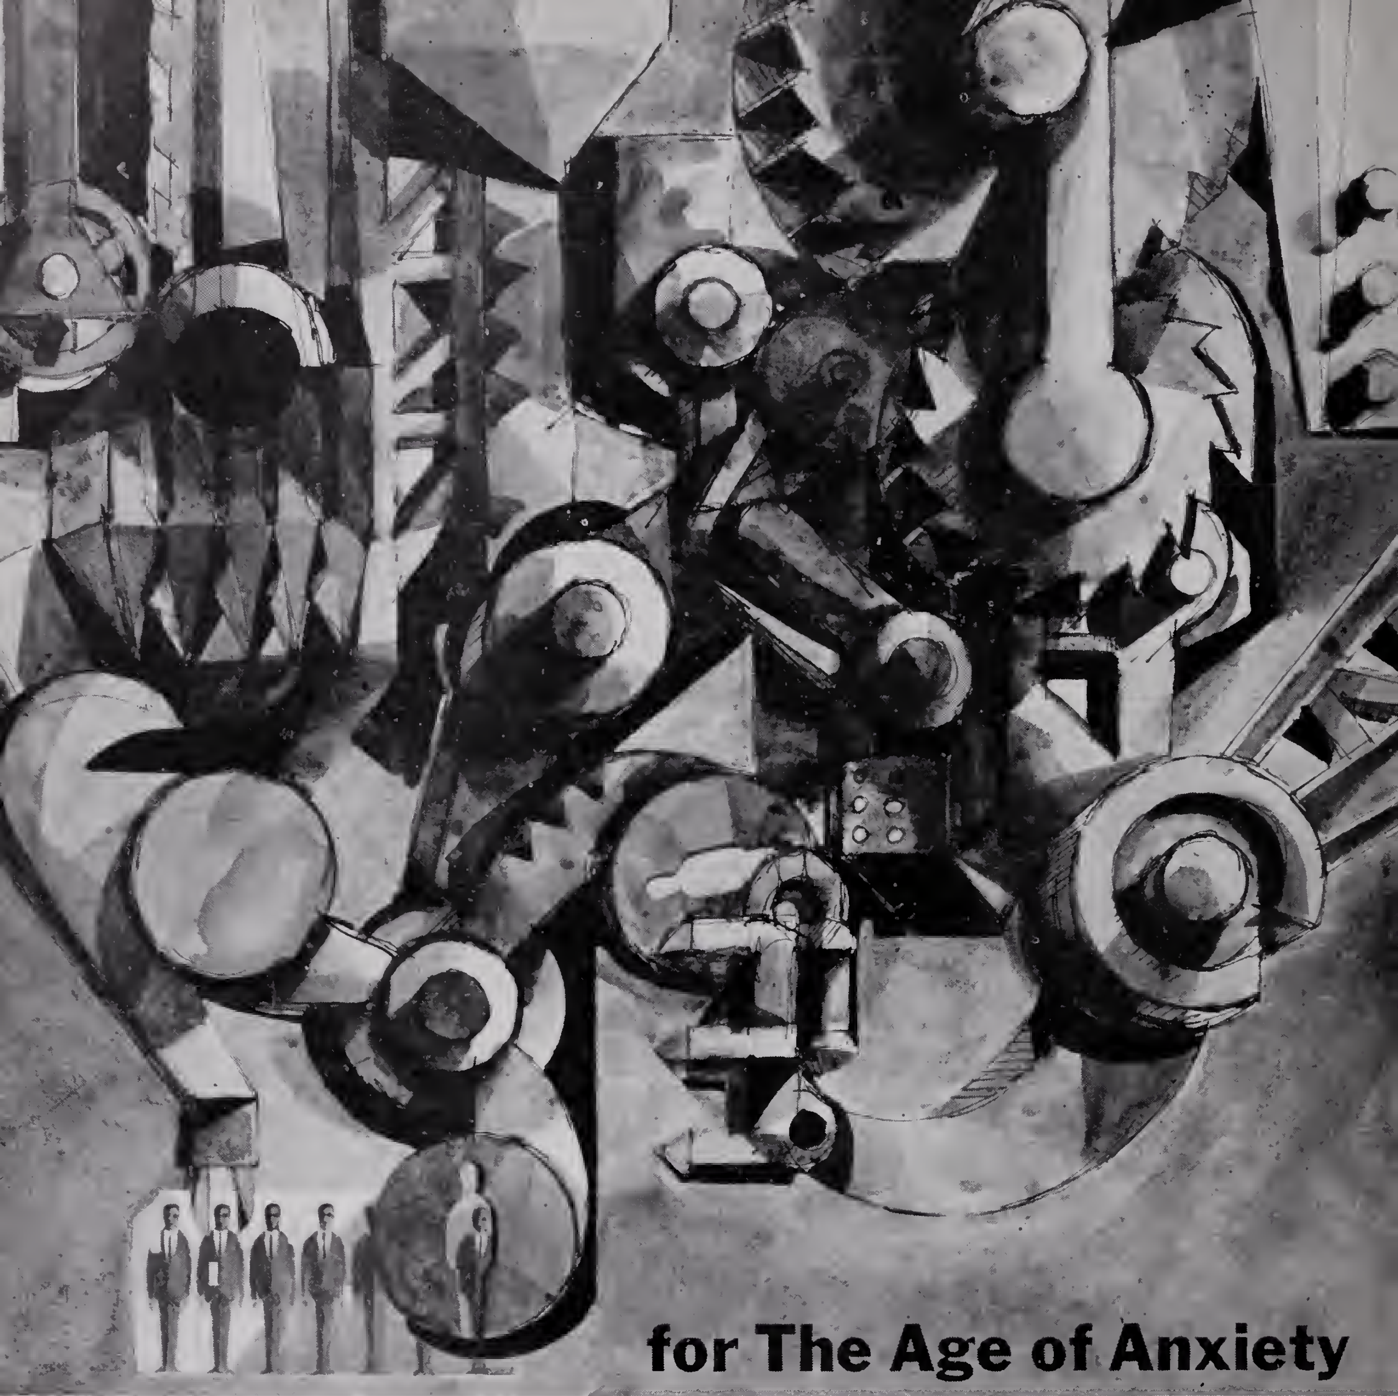
AMES

AMES



for The Age of Anxiety

For those who cannot cope realistically with the emotional turmoil and stress of modern living, the physician has at hand many valuable psychotherapeutic aids. One of the most useful is Librium, a pre-eminent prescription for excessive anxiety in this modern age.

LIBRIUM®(chlordiazepoxide HCl)

5 mg 10 mg 25 mg capsules in #50's

ROCHE

In prescribing: Dosage—Adults: Mild to moderate anxiety and tension, 5 or 10 mg t.i.d. or q.i.d.; severe states, 20 or 25 mg t.i.d. or q.i.d. Geriatric patients: 5 mg b.i.d. to q.i.d. **Side Effects:** Side effects, usually dose-related, include drowsiness, ataxia, minor skin rashes, edema, menstrual irregularities, nausea and constipation. When treatment is protracted, blood counts and liver function tests are advisable. Paradoxical reactions may occasionally occur in psychiatric patients. Individual maintenance dosages should be determined. **Precautions:** Advise patients against possibly hazardous procedures until maintenance dosage is established. Though compatible with most drugs, use care in combining with other psychotropics, particularly MAO inhibitors or phenothiazines; warn patients of possible combined effects with alcohol. Observe usual precautions in impaired renal or hepatic function, in long-term treatment and in presence of depression or suicidal tendencies. Exercise caution in administering drug to addiction-prone patients or those who might increase dosage; withdrawal symptoms, similar to those seen with barbiturates or meprobamate, can occur upon abrupt cessation after prolonged overdosage. Caution should be exercised in prescribing any therapeutic agent for pregnant patients. **Supplied:** Capsules, 5 mg, 10 mg and 25 mg, bottles of 50.

new from Ames
5 basic uro-analytical facts in 30 seconds

Labstix®
BRAND REAGENT STRIPS

...broadest urine screening possible from a single reagent strip

Urine test results with Labstix Reagent Strips can represent significant guides to differential diagnosis or therapy in many conditions. An unexpected "positive" may enable you to detect hidden pathology—long before more recognizable symptoms become evident. Negative results, which permit you to rule out abnormalities in a broad clinical range, can serve as baseline values for reference in future examinations. The 5 colorimetric test areas encompassed on Labstix Reagent Strips are:

pH—values are read numerically in the essential range of pH 5 to pH 9.

Protein—results are read either in the "plus" system or in mg. % in amounts approximating "trace," 30, 100, 300, and over 1000 mg. %.

Glucose—provides a "Yes-or-No" answer for urine "sugar spill."

Ketones—detects ketone bodies in urine—**both** acetoacetic acid and acetone. Reacts with as little as 5 to 10 mg. % of acetoacetic acid.

Occult Blood—specific test for intact red cells, hemoglobin or myoglobin. Results are read as negative, small, moderate or large amounts.

Now a Clear Reagent Strip of Firm Construction

...facilitates handling during testing procedure. Excellent color contrast made possible by the clear plastic strip, together with the clearly defined color charts provided, permits precise, reproducible colorimetric readings in all 5 test areas. A more definitive interpretation of uro-analytical facts is made possible.

Available: Labstix Reagent Strips, bottles of 100 (color charts are supplied with each bottle).

The Somatic Mask: chest pain—heart disease or psychic tension?

Precordial pain as well as tachycardia, palpitation, breathlessness and faintness or arrhythmias are classic signs of cardiac disease. In many cases, however, they may represent a "somatic mask"—a psychophysiological equivalent of psychic tension.

Valium (diazepam) reduces the patient's disturbing psychic tension and helps improve such related symptoms as sadness and feelings of hopelessness, fatigue, insomnia, crying spells and nervousness.

In prescribing: Dosage — Adults: Mild to moderate psychoneurotic reactions, 2 to 5 mg b.i.d. or t.i.d.; severe psychoneurotic reactions, 5 to 10 mg t.i.d. or q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hrs, then 5 mg t.i.d. or q.i.d. as needed; muscle spasm with cerebral palsy or athetosis, 2 to 10 mg t.i.d. or q.i.d. Geriatric patients: 1 or 2 mg/day initially, increase gradually as needed.

Contraindications: Infants, patients with history of convulsive disorders or glaucoma.

Warning: Not of value in the treatment of psychotic patients, and should not be employed in lieu of appropriate treatment.

Precautions: Limit dosage to smallest effective amount in elderly patients (not more than 1 mg, one or two times daily) to preclude ataxia or oversedation. Advise patients against possibly hazardous procedures until correct maintenance dosage is established; driving during therapy not recommended. In general, concurrent use with other psychotropic agents is not recommended. Warn patients of possible combined effects with alcohol. Safe use in pregnancy not established. Observe usual precautions in impaired renal of hepatic function and in patients who may be suicidal; periodic blood counts and liver function tests advisable in long-term use. Cease therapy gradually.

Side effects: Side effects (usually dose-related) are fatigue, drowsiness and ataxia. Also reported: mild nausea, dizziness, blurred vision, diplopia, headache, incontinence, slurred speech, tremor and skin rash; paradoxical reactions (excitement, depression, stimulation, sleep disturbances and hallucinations) and changes in EEG patterns. Abrupt cessation after prolonged overdosage may produce withdrawal symptoms similar to those seen with barbiturates, meprobamate and chlordiazepoxide HCl.

Supplied: Tablets, 2 mg, 5 mg and 10 mg; bottles of 50.
